### Introduction

- Availability is a very large subject
  - > We won't be covering everything
- Not just HA technology anything that can cause an outage is significant
  - > This might be an overloaded system, etc
  - We will only be covering HA technology
- You can have the best HA technology in the world, but you have to manage it correctly
- HA technology is not a substitute for good planning and testing!

SHARE in Boston

#### Introduction

correct hardware and
onsider anything that
chine, but it could just be
•

☐ Just because you have implemented an HA environment doesn't mean you can avoid testing!

S

#### Some terms

- Downtime
  - > A period when the system is unavailable
- Single Point of Failure (SPOF)
  - > A part of a system whose failure prevents the entire system from working
- High Availability (HA)
  - > Ensuring a certain (high) level of operational continuity for users of a system
- Redundancy
  - > Additional instances of a critical component
- Heartbeating
  - > Regular verification that an active system is still available
- High availability cluster
  - > A cluster of computer systems designed to give high availability. Typically, some degree of redundancy, heartbeating and automation are provided.

SHARE in Boston

#### Some terms

- Failover
  - > Automatic switching of availability to a standby server
- Switchover
  - > Controlled switching of availability to a standby server
- Failback
  - > Restoration of a system back to its pre-failure state
- Disaster Recovery (DR)
  - Recovery of availability following major system or site disaster, sometimes with an amount of data loss
- Continuous Availability
  - > Ensuring complete operational continuity for users of a system

### What are you trying to achieve?

- The objective is to achieve 24x7 availability of messaging
- Not always achievable, but we can get close
  - > 99.9% availability = 8.76 hours downtime/year
  - > 99.999% = 5 minutes
  - > 99.9999% = 30seconds
- Potential outage types:
  - > 80% scheduled downtime (new software release, upgrades, maintenance)
  - > 20% unscheduled downtime (source: Gartner Group)
    - 40% operator error
    - 40% application error
    - 20% other (network failures, disk crashes, power outage etc.)
- Avoid application awareness of availability solutions

SHARE in Boston

## What are you trying to achieve?

	-	S H A R I Technology - Connections - Result
N		The objective is to achieve 24x7 availability of messaging. Applications should be processing messages continuously, regardless of any failures in any component. This presentation concentrates on the MQ and MB element, but they are not the only areas to think about.
0		Availability is not necessarily the same as ensuring processing of each and every message. In some situations, some limited message loss is acceptable provided that availability is maximised For example, a message might expire or be superseded during an outage. Here, the important thing is to ensure that messages are still getting through.
Т	٥	Service Level Agreements (SLAs) should define what level of availability your applications and services should provide. The level of availability is often measured by the number of 9s.
	٥	HA solutions should increase availability given scheduled or unscheduled downtime. Scheduled downtime is more common than unscheduled. Availability issues usually involve a multitude of hardware and software systems.
Е	٥	Avoid application awareness of availability solutions and aim to have little or no code in the application managing the environment. That's a task better left to systems administrators.
S		

### Single Points of Failure

- With no redundancy or fault tolerance, a failure of any component can lead to a loss of availability
- Every component is critical. The system relies on the:
  - > Power supply, system unit, CPU, memory
  - > Disk controller, disks, network adapter, network cable
  - > ...and so on
- Various techniques have been developed to tolerate failures:
  - > UPS or dual supplies for power loss
  - > RAID for disk failure
  - > Fault-tolerant architectures for CPU/memory failure
  - > ...etc
- Elimination of SPOFs is important to achieve HA

### Single Points of Failure

There are several techniques and technologies used to eliminate SP redundant systems and hardware components.	POFs, such	as deployment o

☐ Any part of a system whose failure can make the system unavailable is single point of failure.

S

SHARE in Boston

### **Queue Manager Clusters**

- Sharing cluster queues on multiple queue managers prevents a queue from being a SPOF
- Cluster workload algorithm automatically routes traffic away from failed queue managers

SHARE in Boston

### **Queue Manager Clusters**

- ☐ Although queue manager clustering does provide some facilities useful in maintaining availability of messaging, it is primarily a parallel processing feature. It is simple to deploy extra processing power in the cluster to process more messages.
- ☐ If a queue manager in a cluster fails, the failure can be mitigated by other cluster queue managers hosting instances of the cluster queues. Messages are marooned on the failed queue manager until it restarts, but messaging through the cluster is still operational.

Ε

Ν

0

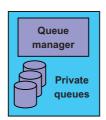

Τ

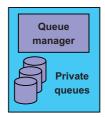

S

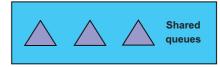

### **Queue-Sharing Groups**

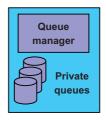

- On z/OS, queue managers can be members of a queue-sharing group
- Shared queues are held in a coupling facility
  - All queue managers in the QSG can access the messages
- Benefits:
  - Messages remain available even if a queue manager fails
  - > Pull workload balancing
  - > Apps can connect to the group

SHARE in Boston

### **Queue-Sharing Groups**

In the queue-sharing group environment, an application can connect to any of the queue managers within the queue-sharing group. Because all the queue managers in the queue-sharing group can access the same set of shared queues, the application does not depend on the availability of a particular queue manager; any queue manager in the queue-sharing group can service any queue. This gives greater availability if a queue manager stops because all the other queue managers in the queue-sharing group can continue processing the queue.

☐ To further enhance the availability of messages in a queue-sharing group, WebSphere MQ detects if another queue manager in the group disconnects from the Coupling Facility abnormally, and completes units of work for that queue manager that are still pending, where possible. This is known as peer recovery.

S

E

Τ

### Support for networked storage

- Support has been added for queue manager data in networked storage
  - > NAS so that data is available to multiple machines concurrently
    - Already have SAN support
  - Added protection against concurrent starting two instances of a queue manager using the same queue manager data
  - > On Windows, support for Windows network drives (SMB)
  - On Unix variants, support for Posix-compliant filesystems with leased file locking
    - NFS v4 has been tested by IBM
    - Currently, Solaris has some issued with some network-attached storage systems.
- · Some customers have a "no local disk" policy for queue manager data
  - > This is an enabler for some virtualized deployments
  - Allows simple switching of queue manager to another server following a hardware failure

### Support for networked storage

	_	I facilities Considerate Means
N		While not directly an HA technology, this is an enabler for customers who want to place all of the data remote from their servers such that it becomes possible to replace one server with another in the event of a failure.
		Support has been added for networked (NAS) storage for queue manager data and logs. Previously, it's been supported for error and trace directories, and for installation binaries.
О		On Unix platforms, we support Posix-compliant filesystems which supports lease-based file locking. The lease-based locking ensures that files unlock when the server running a queue manager fails. This rules out NFS v3 for use in an HA environment because the file locks are not released automatically for some failures and this will prevent failover.
ı		On Solaris please see the following link for known issues: <a href="http://www-">http://www-</a>
E		01.ibm.com/support/docview.wss?rs=171&context=SSFKSJ&context=SSEP7X&q1=cryptography &uid=swg21398427
		On Unix, we have provided a test program (amqmfsck) which checks out the filesystem's behavior. If the tests do not pass, a queue manager using the filesystem will not behave correctly. Output from this program can be used to diagnose a failure.
S		On Windows, we support Windows network drives (SMB – server message block).

#### Introduction to Failover and MQ

- Failover is the automatic switching of availability of a service
  - > For MQ, the "service" is a queue manager
- Traditionally the preserve of an HA cluster, such as HACMP
- Requires:
  - > Data accessible on all servers
  - > Equivalent or at least compatible servers
    - Common software levels and environment
  - > Sufficient capacity to handle workload after failure
    - Workload may be rebalanced after failover requiring spare capacity
  - > Startup processing of queue manager following the failure
- MQ offers two ways of configuring for failover:
  - > Multi-instance queue managers
  - > HA clusters

### Introduction to Failover and MQ

Requirement to access data

• Shared disks – for an H.

· Shared disks - for an HA cluster, usually "switchable" between the servers

• Mirrored disks – must be truly synchronized mirror for integrity

Requirement for client connectivity

· IP address takeover (IPAT) is generally a feature of failover environments

 If a queue manager changes IP address, intelligent routers can hide this or MQ network configuration can be defined with alternative addresses

Servers must be equivalent

- Common software levels or at least compatible, to allow for progressive upgrade of the servers
- · Common environments paths, userids, security

□ Sufficient capacity to handle workload

 Often, workload will be redistributed following a failover. Often, the systems are configured for mutual takeover where the workload following failover is doubled since the surviving servers must handle the traffic intended for both.

S

0

Τ

Ε

### Failover considerations

- Failover times are made up of three parts:
  - > Time taken to notice the failure
    - Heartbeat missed
    - Bad result from status query
  - > Time taken to establish the environment before activating the service
    - Switching IP addresses and disks, and so on
  - > Time taken to activate the service
    - This is queue manager restart
- Failover involves a queue manager restart
  - > Nonpersistent messages, nondurable subscriptions discarded
- For fastest times, ensure that queue manager restart is fast
  - > No long running transactions, for example

S		

- Basic failover support without HA cluster
- New in 7.0.1 on distributed
- Two instances of a queue manager on different machines
  - > One is the "active" instance, other is the "standby" instance
  - > Active instance "owns" the queue manager's files
    - Accepts connections from applications
  - > Standby instance monitors the active instance
    - Applications cannot connect to the standby instance
    - If active instance fails, standby performs queue manager restart and becomes active
- Instances are the SAME queue manager only one set of queue manager data
  - > Queue manager data is held in networked storage

### Multi-instance Queue Managers

	_	SHARE Technology - Connections - Insurin
N	□ "Basic failover": no coordination with other resources like disks, IP addresses, databases, user applications. There is also no sophisticated control over where the queue managers run and more to (like a 3-node HACMP cluster, for example). Finally, once failover has occurred, it is necessar to manually start a new standby instance.	
0		Only one standby instance is supported.
		Architecturally, this is essentially the same as an existing HACMP/VCS setup, with the data shared between systems. It does not give anything "stronger" in terms of availability – but we do expect the typical takeover time to be significantly less. And it is much simpler to administer.
Т		Just as with a configuration using an HA cluster, the takeover is in essence a restart of the queue manager, so nonpersistent messages are discarded, queue manager channels go into retry, and so on.
Е		

### Setting up a Multi-instance Queue Manager

- 1. Set up shared filesystems for QM data and logs
- 2. Create the gueue manager on machine1
  - crtmqm -md /shared/qmdata -ld /shared/qmlog QM1
- 3. Define the queue manager on machine2 (or edit mgs.ini)
  - addmqinf -vName=QM1 -vDirectory=QM1 -vPrefix=/var/mqm -vDataPath=/shared/qmdata/QM1
- 4. Start an instance on machine 1 it becomes active
  - strmqm -x QM1
- 5. Start another instance on machine2 it becomes standby
  - strmqm -x QM1
- That's it. If the queue manager instance on machine 1 fails, the standby instance on machine2 takes over and becomes active
- On Windows, all instances must run on domain controllers

SHARE in Boston

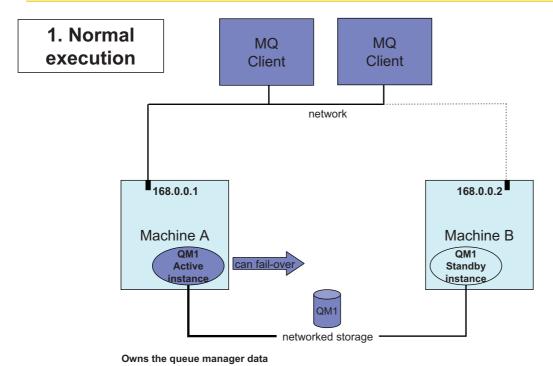

### Setting up a Multi-instance Queue Manager

	Technology - Connections - Results
Z	Create the filesystems in networked storage and mount on the machines to run the queue manager instances. The networked storage must be mounted at the same location on the machines appropriate file permissions so that MQ can create the queue manager. Typically, a pair of filesystems would be used, one for the queue manager data and one for the logs.
0	Create the queue manager on one machine specifying the DataPath (-md) and LogPath (-ld) parameters as directories on the networked storage.
т	Define the queue manager on the other machine. This involves creating a QueueManager stanza in mqs.ini. The new addmqinf command can be used to do that if you don't want to edit the file directly. On Windows, addmqinf creates the equivalent entries in the registry.
	Start the first instance. You need to use '-x' to indicate that you want to start an instance of a multi-instance queue manager. If you omit '-x', the queue manager starts but it will not "permit" a standby instance – it's not a multi-instance queue manager.
Е	Start the second instance. You also need to use '-x' to indicates that you want to start an instance of a multi-instance queue manager. If you omit '-x', the command fails because the queue manager is already running. If you specify '-x', the command starts a standby instance.

Owns the queue manager data

SHARE in Boston

## Multi-instance Queue Managers

4. Recovery complete

Owns the queue manager data

- MQ is NOT becoming an HA cluster
  - > If other resources need to be coordinated, you need an HA cluster
  - > WebSphere Message Broker will integrate with multi-instance QM
  - Queue manager services can be automatically started, but with limited control
- The IP address of the queue manager changes when it moves
  - MQ channel configuration needs list of addresses unless you use external IPAT or an intelligent router
  - > Connection name syntax extended to a comma-separated list
    - CONNAME('168.0.0.1,168.0.0.2')
- System administrator is responsible for restarting another standby instance when failover has occurred

SHARE in Boston

## Administering a Multi-instance Queue Manager

- All queue manager administration must be performed on the active instance
- dspmq enhanced to display instance information

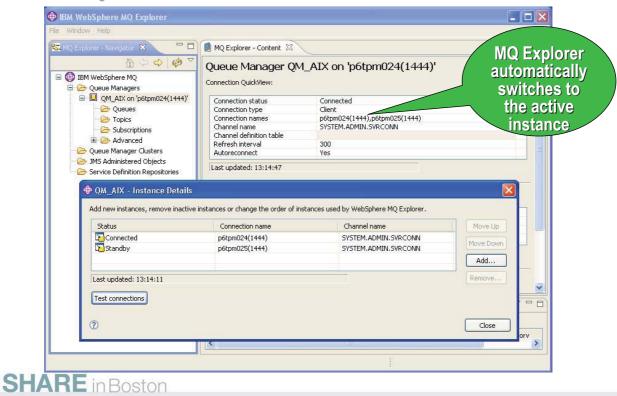

```
$ hostname
staravia
$ dspmq -x
QMNAME(MIQM) STATUS(Running as standby)
    INSTANCE(starly) MODE(Active)
    INSTANCE(staravia) MODE(Standby)
```

- dspmq issued on "staravia"
- > On "staravia", there's a standby instance
- > The active instance is on "starly"

#### **HA clusters**

- MQ traditionally made highly available using an HA cluster
  - > IBM PowerHA for AIX (formerly HACMP), Veritas Cluster Server, Microsoft Cluster Server, HP Serviceguard, ...
- HA clusters can:
  - > Coordinate multiple resources such as application server, database
  - > Consist of more than two machines
  - > Failover more than once without operator intervention
  - > Takeover IP address as part of failover
  - > Likely to be more resilient in cases of MQ and OS defects
- SupportPac MC91 has been withdrawn
  - > Existing MC91 will work, but is not really appropriate any more
  - > New commands allow for simpler taker over, will be described in the info center.

#### **HA clusters**

- In an HA cluster, queue manager data and logs are placed on a shared disk
  - > Disk is switched between machines during failover
- The queue manager has its own "service" IP address
  - > IP address is switched between machines during failover
  - Queue manager's IP address remains the same after failover
- The queue manager is defined to the HA cluster as a resource dependent on the shared disk and the IP address
  - During failover, the HA cluster will switch the disk, take over the IP address and then start the queue manager

#### **HA clusters**

The collection of servers that makes up a failover environment is known as a cluster.	The
servers are typically referred to as nodes.	

- One node runs an application or service such as a queue manager, while the HA cluster monitors its health. The following example is called a cold standby setup because the other nodes are not running workload of their own. The standby node is ready to accept the workload being performed by the active node should it fail.
- ☐ A shared disk is a common approach to transferring state information about the application from one node to another, but is not the only solution. In most systems, the disks are not accessed concurrently by both nodes, but are accessible from either node, which take turns to "own" each disk or set of disks. In other systems the disks are concurrently visible to both (all) nodes, and lock management software is used to arbitrate read or write access.
- □ Alternatively, disk mirroring can be used instead of shared disk. An advantage of this is increased geographical separation, but latency limits the distance that can be achieved. But for reliability, any transaction logs must be the same which means any synchronous disk writes must also be sent down the wire before being confirmed.

- ☐ This configuration is also sometimes called a "mutual takeover" system
- □ In normal operation, both machines are running independent queue managers. If one of the systems fails, then this configuration can migrate the failed queue manager to the working machine. So it still appears to applications outside the cluster that you have 2 queue managers. The throughput of each queue manager may degrade (depending on how heavily loaded they run) but at least the work is still getting done.
- ☐ With this kind of setup, you probably have a failback capability so that the queue manager can be sent back to its original node when the failure has been corrected. Whether the failback is automatic or not may be your choice, but I'd strongly recommend that it's done manually so that applications which have already connected to the running queue manager do not have their connections broken arbitrarily. You probably want to monitor the workload and only failback when there's not too much work that's going to be disrupted by the failback.
- □ A number of variations on the themes of cold and hot standby are also possible, for example having 3 nodes to host 2 queue managers (an "N+1" configuration). The availability of these options will depend on the facilities available in your cluster software.
- ☐ In this configuration, we've shown the IP address associated with each queue manager being migrated. You will also need to keep a port number reserved for each queue manager (the same number on both machines in the cluster), and have appropriate setup for runmqlsr or a queue-manager listener object.

SHARE in Boston

### Multi-instance QM or HA cluster?

- Multi-instance queue manager
  - ✓ Integrated into the WebSphere MQ product
  - √ Faster failover than HA cluster and MC91
    - Delay before queue manager restart is much shorter
  - Runtime performance of networked storage
  - More susceptible to MQ and OS defects
- HA cluster
  - √ Capable of handling a wider range of failures
  - ✓ Multiple resource managers supported
  - √ Failover historically rather slow, but some HA clusters are improving
  - Some customers frustrated by unnecessary failovers
  - Require MC91 SupportPac or equivalent configuration
  - Extra product purchase and skills required

Page intentionally left blank

## **Comparison of Technologies**

	Access to existing messages	Access for new messages
Shared Queues, HP NonStop Server	continuous	continuous
MQ Clusters	none	continuous
	automatic	continuous
HA Clustering, Multi-instance	automatic	automatic
No special support	none	none

SHARE in Boston

## **Comparison of Technologies**

This picture shows one view of the different capabilities. However you also need to consider
factors such as total hardware/software price, the requirement for nonpersistent message
availability (remember that they are discarded by a failover-restart), and the requirement for
persistent message availability (not if you're using the shared queue support)

## How to make your own applications HA

- Application environment
  - > What does the application depend on
- Application design
  - > Affinities implicit in the application design
  - Message loss
- MQ connectivity
  - > What happens when the application loses connectivity

Page intentionally left blank

## HA applications Application environment

- · Simple applications only need a queue manager connection
- Many business applications have dependencies, such as:
  - > Database instance, message broker, application server
  - > Configuration information
  - > Some data is machine-specific, other data is server-specific
  - > Get the ordering of dependencies and timing correct
- How can you tell if it's working
  - > Such as PING QMGR
  - > Remember that restart might take a little while
- Start/stop operations need to be robust
  - Don't rely on anything!
  - > Remember that a 'stop' command might erroneously block
- If you want to put your app in an HA cluster, you'll need to answer these

SHARE in Boston

## HA applications Application environment

A	bk	dication environment	SHARE Technology - Connections - Results
N	٥	Having a highly available queue manager is not a lot of use unless there are applications which are go dealing with the messages. So you need to also think about how you are going to make your application available.	
0	٥	If you take an education class on something like HACMP then you will be taught how to do this. Howe gives some high-level critical design steps you should look at, based on our experiences of making the SupportPacs for MQ and the message brokers.	
	٥	First off, you need to work out the unit of failover. This will probably be an instance of the "application is a single executable process or perhaps a related group of processes. This program is often tied to a queue manager or broker (perhaps it's a command line option).	•
Т		What configuration information needs to be moved around with the application? Is there some that is r specific (and hence should not move) and is there some that is instance-specific. Is there any synchro required between 2 machines? Where is the config information stored? In a file or in a system registry	nization ?
E		If you are going to be actively monitoring the health of your application so you can recover if it should the actual test you will apply? Checking for a process running? Looking to see if a file exists? Remember program is updating a file with its status, you might not be able to rely on that information if the program Start and Stop commands need to be able to recover from just about any state the application is in. W might try a 'graceful' stop, this may need to be repeated in a more forceful way if the operation does not in a reasonable time. You might need to do some kind of synchronization between Start and the initial to ensure you don't report a failure just because there's a slow restart.	per that if a m abends. hile you ot complete
S	٥	Doing operations asynchronously within the HA framework is often a good idea, so that other compone system can also be monitored or restarted simultaneously. Again though, you might have some depend a database) to wait for	

## HA applications Application affinities

- Affinities can be introduced by:
  - > The need to continue using the same instance of a service
  - Multiple messages sent to the same application process
  - Conversational-style applications
- Try to avoid!
  - Affinities cause problems with availability and WLM
  - > Also difficulties using generic channels or ports on z/OS
- Carry any transient state in the message
  - > And replicate frequently-read data
- Let other components handle partitioning or sharing of data
  - > e.g. store state in a parallel database
- MQ clusters can handle application affinity requirements
  - > Use BIND ON OPEN option
  - > Maybe program a workload exit to remember previous messages

SHARE in Boston

## HA applications Message loss

- Does your application really need every message delivered?
  - > If so, it's quite fragile to failures
  - > Queue manager restart will lose nonpersistent messages
  - Message expiry discards old messages
  - > Typically, disaster recovery (DR) situations involve message loss
- By careful design of the messages and applications, it is often possible to keep messaging even without failover
  - Some customers use workload balancing and application redundancy instead

## HA applications MQ connectivity

- If an application loses its connection to a queue manager, what does it do?
  - > End abnormally
  - > Handle the failure and retry the connection
  - > Reconnect automatically thanks to application container
    - WebSphere Application Server contains logic to reconnect
  - > Use MQ automatic client reconnection

### Automatic client reconnection

- MQ client automatically reconnects when connection broken
  - > MQI C clients and JMS clients
- Reconnection includes reopening queues, remaking subscriptions
  - All MQI handles keep their original values
- Can connect back to the same queue manager or another, equivalent queue manager
- MQI or JMS calls block until connection is remade
  - > By default, will wait for up to 30 minutes
  - > Long enough for a queue manager failover (even a really *slow* one)

#### Automatic client reconnection

- Can register event handler to observe reconnection
- Not all MQI is seamless, but majority repaired transparently
  - > Browse cursors revert to the top of the queue
  - > Nonpersistent messages are discarded during restart
  - > Nondurable subscriptions are remade and may miss some messages
  - > In-flight transactions backed out
- Tries to keep dynamic queues with same name
  - If queue manager doesn't restart, reconnecting client's TDQs are kept for a while in case it reconnects
  - > If queue manager does restart, TDQs are recreated when it reconnects

### **Automatic client reconnection**

- Enabled in application code or ini file
  - > MQI: MQCNO\_RECONNECT, MQCNO\_RECONNECT\_Q\_MGR
  - > JMS: Connection factories/activation specification properties
- Plenty of opportunity for configuration
  - > Reconnection timeout
  - > Frequency of reconnection attempts
- Requires:
  - > Threaded client
  - > 7.0.1 server
  - > full-duplex client communications (SHARECNV >= 1)

### Making file transfers highly available

- Since version 7.0.2 WMQFTE has had support for MQ Multi-Instance queue managers
- Configurable for coordination queue managers and agent queue managers.
- Done through the properties file
- If the multi-instance queue manager fails over to the standby then the agent will attempt to connect to the standby instance.
- Also works for the database logger tool http://publib.boulder.ibm.com/infocenter/wmqfte/v7r0/topic/com.ibm.wmqfte.admin.doc/high\_availability\_qms.htm

SHARE in Boston

### Making file transfers highly available

N	Version 7.0.2 of WebSphere MQ File transfer Edition introduced the ability to configure MQ multi-instance queue manager capability for the following types of
	queue manager:
	Coordination
	• Agent

☐ The database logger feature can also use an MQ multi-instance queue manager

☐ This is fully documented in the online Information center here: http://publib.boulder.ibm.com/infocenter/wmqfte/v7r0/topic/com.ibm.wmqfte.admin.doc /high\_availability\_qms.htm

### Use of MQ HA by Message Broker

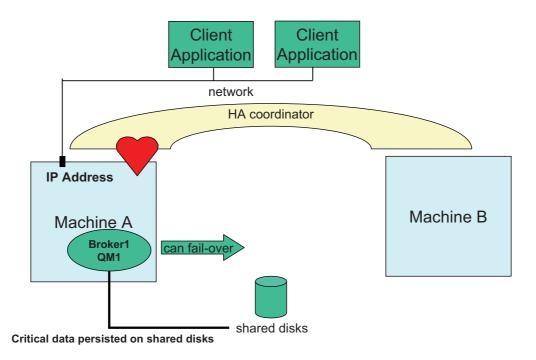

- How is it achieved on Broker.
  - Broker "Global" Data is retained on shared network storage
    - Broker Registry
    - Components directory Configuration Store
    - Logs, errors and shared-classes remain on local machine.
  - Software HA Support for Broker uses Multi-Instance Queue Managers
    - Pre-requisite : MQ v7.0.1.0 which delivered :
      - Multi-Instance queue manager
      - Automatic client reconnect

## High Availability Cluster Coordination

- active / passive machines

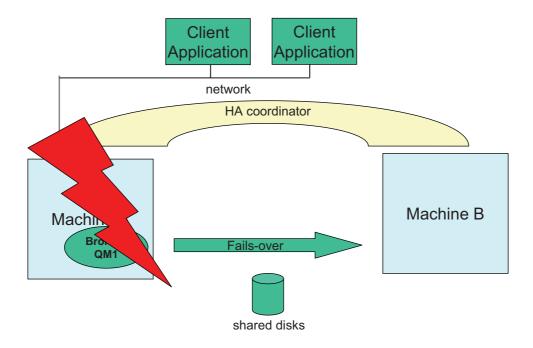

#### **High Availability Cluster Coordination**

#### - a failure occurs

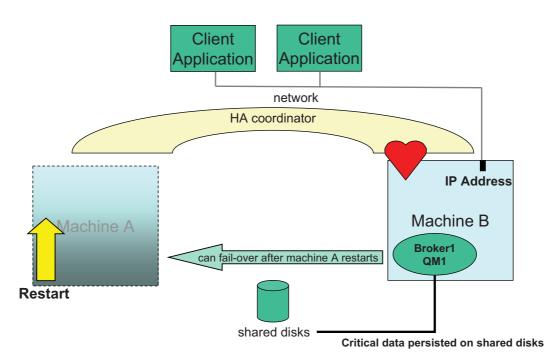

SHARE in Boston

## High Availability Cluster Coordination - broker fails over to machine B

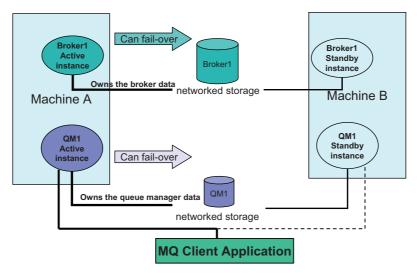

## Software HA Support - multi-Instance broker Using multi-instance queue manager

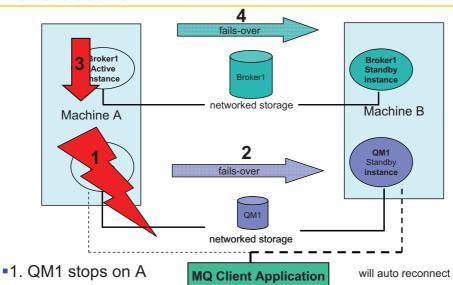

- No need for external HA co-ordinator
- Broker relies on queue manager fail-over capability
- •Failover will occur when active queue manager terminates / stops

### SHARE in Boston

#### Software HA Support

- a failure occurs

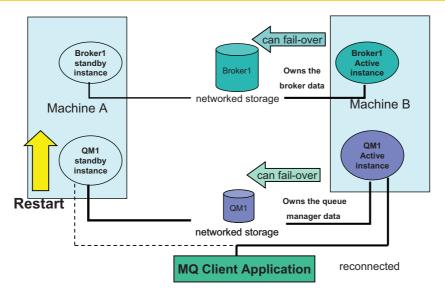

- •2. QM1 fails-over to machine B
- 3. Broker1 detects QM1 has stopped. Moves to Standby on machine A
- •4. Broker1 fails-over to machine B

#### Software HA Support

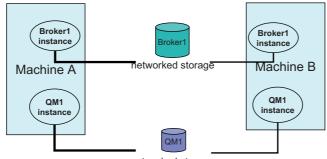

- Recovery is complete on machine B. Broker1 and QM1 are active
- Restart QM1 on machine B in standby mode. BK1 still in standby mode

### **Configuration – The Broker**

- Create multi-instance broker "Broker1" on node A
  - -> mqsicreatebroker Broker1 -q QM1 -e <shared network directory>
  - > creates shared registry and configuration data on shared network storage
  - > creates local registry reference to shared network path
  - > logs ,error data and shared-classes remain on local machine
- Create broker instance "Broker1" on node B
  - ->mqsiaddbrokerinstance Broker1 -e <shared network directory>
  - > References the broker configuration on the shared network directory
  - > Creates local registry reference to shared network path
  - > logs, error data and shared-classes remain on local machine

networked storage

#### **Runtime**

#### - Displaying status of multi-instance broker

#### Run mqsilist on Node A

->mqsilist

BIP1295I: Broker 'Broker1' is a multi-instance broker running in active mode on multi-instance queue manager 'OM1'.

BIP8071I: Successful command completion.

#### Run mqsilist on Node B

->mqsilist

BIP1294I: Broker 'Broker1' is a multi-instance broker running in standby mode on multi-instance queue manager 'QM1'. More information will be available when the broker instance is active.

BIP8071I: Successful command completion.

### **Summary**

- MQ and operating system products provide lots of options to assist with availability
  - > Many interact and can work well in conjunction with one another
- But it's the whole stack which is important ...
  - > Think of your application designs
  - > Ensure your application works in these environments
- Decide which failures you need to protect against
  - > And the potential effects of those failures
- Also look for RedBooks and read the MQ HA whitepaper
