

ICF Catalog Synchronization at the Disaster Recovery Site Using Catalog RecoveryPlus

Janet Sun
jsun@mainstar.com
August 5, 2010

Agenda

- The Problem
- Analysis – Disaster Recovery Review
- The Solution
- Implementing the Solution
 - Using Full Catalogs
 - Using Empty Catalogs

The Problem

- When data is recovered at the Disaster Recovery (DR) site, the entries in the catalog are not necessarily synchronized with the actual data sets that are recovered
- Catalog entries may indicate a data set resides on a different volume than where it was actually recovered
- Catalog entries may exist for data sets which do not exist
 - Not all data sets will be recovered at the DR site

The Problem

APPLA.FILE VOL1
APPLB.FILE VOL3
Home site

APPLA.FILE VOL1
APPLB.FILE VOL3
DR Site

The Problem

- This can result in allocation failure or job failure when accessing the data set

```
//DD1 DD DSN=APPLA.FILE,DISP=OLD
```

APPLA.FILE VOL1
APPLB.FILE VOL3

What Is the Purpose of Disaster Recovery?

SHARE in Boston

Disaster Recovery Objective

- Facilitate business continuity at your disaster recovery site
 - Get up and running as quickly as possible with all key business applications

Simplistic Approach

- As simple approach would be to take a complete image of everything at a point-in-time with all data static
 - All application and user access stopped for the duration of time required to copy all of the data
- Is there a problem with this?

Copy All Volumes

Not Practical

- Need all applications quiesced
- Takes too long to dump all volumes with all applications quiesced
- Would be taking more data to DR site than actually needed for business continuity
- Costs more for off-site storage of tapes or DASD for mirroring for entire data center
- Costs more for DASD usage at DR site

There Is a Better Option...

SHARE in Boston

Selective Approach

- Makes more sense to back up only the data needed for business continuity
- Categorize data into groups:
 - Operating system and support data
 - Business applications
 - Test, TSO, temporary work data
- Also useful to group data this way when planning for mirroring volumes

Data Groups

- System data
 - Fairly static except when upgrades done
 - Some files dynamic, need additional consideration
- Business application data
 - Dynamic, created, deleted, changed frequently
- Test, TSO data
 - Not needed to keep business going

System Data

- Take full volume dumps of system volumes
- Take more frequent backups of dynamic system data sets
 - ICF catalogs
 - Security database
 - Tape management database
 - Databases for other key products
- This data will be the first group to be recovered at DR

Application Data

- Data will be backed up in logical groups by application function for synchronization purposes
- More application data than system data

Our Goal

- Ensure that the entries in the ICF catalogs match the data sets that are actually recovered

Easier said than done...

You Must Have a Plan

SHARE in Boston

Recovery Plan

- Full volume recoveries of system volumes
- Individual data set recoveries for dynamic system files, includes catalogs that reside on volumes recovered
- How can we get the catalogs synchronized with what we have recovered so far?

Recovering Catalogs

- Catalogs can be recovered either through full volume restore or can be recreated from scratch
- The two methods of synchronizing catalogs depend on whether you are starting with:
 - Full catalogs
 - or
 - Empty catalogs

Full Catalogs

SHARE in Boston

Full Catalogs

- Most useful to start with full catalogs when they will primarily contain entries for system data sets
- Will probably have full catalogs as the result of a full volume restore or mirroring

Full Catalogs

- Will want to remove the catalog entries for data sets which are not physically at the DR site after full volume restores complete
- Assume that application data restore will attempt to catalog data sets as they are restored

Full Catalogs

- To remove catalog entries for non-existent data sets, you have these options:
 - IDCAMS can be used to delete entries for data sets which have not been recovered once they have been identified
 - The Catalog RecoveryPlus (CR+) CATSCRUB command can be used to delete entries for data sets which have not been recovered as well as handling other types of data set entries

Full Catalogs

- Using IDCAMS
 - Must identify catalog entries that need to be deleted
 - No easy way to accomplish this
 - Could have a user-written program to identify these data sets and build DELETE commands
 - Must run IDCAMS DELETE NOSCRATCH to remove unwanted catalog entries
 - The IDCAMS DELETE commands may take a long time to run

Full Catalogs

- Using CR+
 - The CATSCRUB command is used to synchronize a catalog with the online DASD volumes at the DR site
 - The specific volumes to synchronize against can be controlled by the user
 - CATSCRUB deletes records directly without invoking IDCAMS resulting in faster processing

Example of Run Times

- Deleting 1,814,965 catalog entries at DR:
 - Using IDCAMS and other methods took 15 hours
 - Using CR+ CATSCRUB took 20 minutes

But What About....

SHARE in Boston

Other Considerations

- Some catalog entries that you need to think about
 - Cataloged tape data sets
 - Migrated data sets
 - GDG bases

Other Catalog Entries

- CATSCRUB can handle it all
 - Allows user control over specific types of catalog record situations, including:
 - Migrated data sets
 - Tape data sets
 - GDS not found on volume
 - GDG base without active generations
 - Multi-volume data sets in error
 - Non-VSAM alias entry, but the data set it is associated with is not found
 - Specific data set names
 - Specific VOLSERS

Empty Catalogs

SHARE in Boston

Empty Catalogs

- Most useful to have empty catalogs when they will contain primarily application data set entries
- Assume that application data restore will attempt to catalog data sets as they are restored

Empty Catalogs

- Starting with empty catalogs eliminates synchronization problems between data being restored and catalog entries
 - The only catalog entries will be for data sets which are restored at the DR site

Empty Catalogs

- To create empty catalogs, there are options:
 - IDCAMS DEFINE of the catalog and then DEFINE the aliases to the master catalog
 - CR+ RECOVER with EXCLUDE-DSN to recover the catalog empty and automatically define the aliases to the master catalog

Empty Catalogs

- Using IDCAMS
 - Step 1: Need to define the user catalogs required
 - Must determine how catalogs are currently defined (CI/CA size, space, etc.)
 - DEFINE USERCATALOG commands must be created
 - Job can be set up before arrival at DR site and sent off-site
 - Must keep this job updated whenever a new catalog is defined or an attribute is changed

Empty Catalogs

- Using IDCAMS
 - Step 2: Need to define all of the aliases that should be pointing to each catalog
 - Must determine which aliases should be defined to which catalog
 - DEFINE ALIAS commands must be created
 - Job can be set up before arrival at DR site and sent off-site
 - Must keep this job updated regularly to ensure list of aliases is current and complete

Empty Catalogs

- Using IDCAMS
 - Step 3: At the DR site
 - If catalogs already exist due to full volume restore, then they must be deleted first with RECOVERY
 - Run job to DEFINE catalogs
 - Run job to DEFINE aliases

Empty Catalogs

- Using CR+
 - Step 1: Create a backup of all catalogs to be sent off-site as part of daily DR procedures
 - Back up at least once per day
 - Step 2: At the DR site
 - Run the CR+ RECOVER command with the EXCLUDE-DSN(**) keyword to recover the catalog in an empty state and automatically define the aliases to the master catalog

Empty Catalogs

- Other possible needs when working with empty catalogs:
 - GDG base definitions

GDG Bases

- Options for defining GDG bases:
 - Create (method up to you) a file with all IDCAMS DEFINE GDG commands at the home site and send it to the DR site
 - Job can be set up in advance
 - Must keep the job updated regularly when new GDGs are created
 - Use the CR+ RECOVER command with the INCLUDE-TYPE of EMPTY-GDG to redefine the GDG bases

GDG Bases

- Using IDCAMS
 - Before the disaster or test
 - Run LISTCAT with the GDG parameter to list the entries in the catalog that are GDG bases to a file
 - The file can be post-processed (method up to you) to create the IDCAMS DEFINE GDG commands which can be written to another file
 - Create an IDCAMS job that uses this file as input
 - Run this job at the DR site after the catalogs have been recovered, and before application data recovery begins

GDG Bases

- Using CR+
 - Before the disaster or test:
 - Create a backup of all catalogs to be sent off-site as part of daily DR procedures
 - At the DR site:
 - Using the catalog backup from above, run the RECOVER command with the keyword INCLUDE-TYPE(EMPTY-GDG) to define the catalog with aliases in the master catalog, and empty GDG bases created

Summary

- You will want to use both full and empty catalogs at DR
- For system catalogs, start with **full catalogs** and use CATSCRUB to delete bad entries
- For application catalogs, start with **empty catalogs** and the application restores will correctly catalog the data sets
