

N	Notes:	
	SHARE Technology - Contextion - Structs	
•	In our typical mainframe development, we normally only address mission-critical applications. Because these applications are normally high-volume and are the life-blood of our business, we have surrounded them with procedures with tight controls that insure quality, consistency, availability and all of the other attributes needed for our main applications. These applications are normally written in CICS or WebSphere Application Server which provide industrial-strength environments for our applications.	
•	In addition to the main applications that handle the volume of our user interactions, there are other applications our business needs for special situations such as a sales promotion. Because of the procedures and development techniques we use, we are often not able to address application requests for the special situations (which are commonly referred to as 'situation applications').	
•	The demand for situational applications (sometimes referred to as the 'long tail of demand') at some companies outweighs the requests for traditional requests, but due to the procedures and development techniques we use, we don't have the time and resources to address them.	
•	Even if we had the 'resources', our development techniques often don't allow us to respond quickly enough to accommodate the situational application requests.	
•	CICS Dynamic Scripting is intended to address some of these shortcomings. CICS Dynamic Scripting, built on Project Zero technology provides a productive environment that can be used to address situational applications. CICS Dynamic Scripting is also a great way to introduce new IT staff to CICS via the Project Zero technology, and the PHP and Groovy dynamic scripting languages.

Notes:
S H A R E
• When applied to CICS, HTTP requests go through CICS (so CICS can apply security) and are then passed to the Dynamic Scripting Application. Each Dynamic Scripting application in CICS runs in its own JVMServer. The JVMServer in CICS is a multi-threaded JVM. Any JVM is multi-threaded, however in CICS, each of the threads used for application code are associated with a T8 TCB (the new TCB type for CICS TS V4.1). The reason for the T8 TCBs is that although you can create new threads in a JVM, CICS won't be aware of them unless they are mapped to T8 TCBs. A T8 TCB is needed for application code on the thread to be able to interact with CICS. So, if CICS is creating threads in the JVM, T8 TCBs will be mapped to the threads and code running on those threads can interact with CICS. If an application programmer does a Thread.create() (or similar function), then the thread van't be mapped to a T8 TCB, CICS will be unaware of the thread, and code running on the thread cannot interact with CICS. (Bottom Line: application programmers are discouraged from creating their own threads).
 A Dynamic Scripting application can have "hundreds" of concurrent requests executing in a single JVMServer. Each of these threads would be a concurrent path through the application.
 The JVMServer resource has a THREADLIMIT() parameter where you can specify the max number of threads (T8 TCBs) that can be allocated to the JVMServer. The ThreadLimit on a JVMServer can be from 1-256 with the default being 15. There can be a maximum of 1024 threads for a CICS region. The number of JVMServers will also be influenced by the size of the JVM implemented by the JVMServer resource. These threads are for concurrent application usage. This means that a single JVMServer with 256 threads, depending on the request arrival rate, could be able to handle multiple thousands of users.

	SHARE Technology - Connections - Results
•	The interface to the Project Zero technology implemented in CICS Dynamic Scripting is the same as with any other Project Zero implementation; a command line interface (CLI).
•	The exceptions to the Project Zero command line interface is that the WebSphere sMash Eclipse plug-in allows you to start and stop your application by selecting options from the context menu presented by right-clicking on your WebSphere sMash project. When using the AppBuilder you can access the command line interface through the Web browser interface.
•	The available 'zero' commands are different as to whether you are in an 'application' directory or not. If you are in your application directory you can do commands such as 'zero start', 'zero stop', and 'zero resolve' which go against your application. When outside your application's directory you can use commands like 'zero create' to create a new application.
•	The CLI (command line interface) communicates to CICS using EXCI so the resource definitions supplied with Dynamic Scripting include a CONNECTION definition.
	SHARE
18	© 2011 IBM Corporation

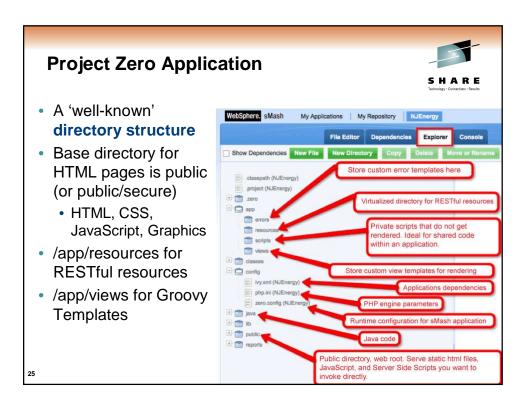

I	Notes:
	Any requested 'zero' commands are run in a JVMServer.
•	In the case of a 'zero start', multiple CICS resource definitions and configuration files are dynamically created.
•	The resource definition names contain two letters and a 6 digit number. The number is maintained in a TSQ named ZEROJID. Since there may be multiple sets of CICS resources at the same time (for different zero commands), each set must be unique.
•	The port that your application will listen on is taken from a config/zero.config file in your application's directory and placed in a TCPIPSERVICE definition. The TCPIPSERVICE resource definition will start with the letters 'TP' or 'TS' depending on whether you are using SSL or not.
•	The JVMServer characteristics will be taken from a configuration from your application's config/zerocics.config file. Some JVM characteristics can be specified, but some options cannot. The JVMServer name will start with the letters 'JC'.
•	A URIMAP definition is created (which starts with either 'UP' or US' depending on whether you are using SSL or not), to direct all incoming HTTP activity from the port specified in the TCPIPService definition to your JVMServer.
•	The URIMAP definition does not point directly to your JVMServer, but points to a PIPELINE definition (starts with 'PI') whose corresponding pipeline configuration file specifies a handler that directs all activity to your JVMServer.
	SHARE
0	© 2011 IBM Corporation

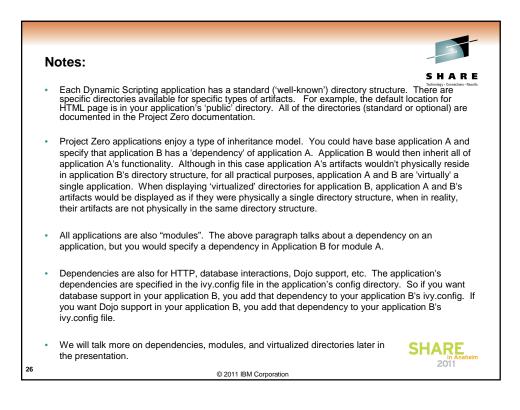

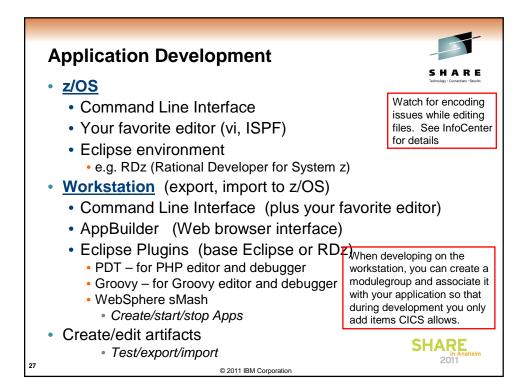

Notes:			
 When CICS starts the JVM running under the control of your JVMSERVER resource, CICS needs to know the JVM's characteristics. As with other JVMs in CICS, the characteristics of the JVM are specified in a JVMProfile file. 			
 This JVMProfile file is dynamically created for you and placed in the JVMPROFILEDIR specified in the SIT (system initialization) parameters. 			
 The contents of JVMProfile file are built from the Command line generated by zero script's (class path, java cmd line options) Information in zerocics.config JVMPROFILE section The zero application's resolved.properties file (LIBPATH) Dynamically created Java system properties defined for use by Java code (z/OS UNIX code page, zero cmd aguments) WORK_DIR set to APP_HOME 			
 A pipeline configuration file used by the PIPELINE resource is placed in your application's .zero/private/cics directory. 			
 The pipeline configuration file contains the JVMSERVER id and a handler. The name of the handler is zero.cics.CicsAdapter. 			
 Note that all resource definitions and configuration files that are dynamically created are also dynamically removed when the JVMServer is shut down. The exception is that you can set an environment variable to tell CICS to leave some of the configuration files and file containing details about the actions that were taken. The name of the environment variable is CICS_DEBUG=ON

•	There are two main configuration files that you will probably need to customize.
•	The zero.config file occurs in every Project Zero module (application) and is in the module's config directory. This configuration file is not specific to CICS, but occurs in every module in every implementation of the Project Zero technology.
•	The slide lists examples of the type of information contained in the zero.config file.
•	The zero.config file contains the port your application will listen on. When your application is created this port is set to 8080 so it is likely that you will want to change the port. The port specified in the zero.config file will be used in the TCPIPSERVICE definition CICS dynamically creates for your application.
•	There is also a zerocics.config file. There is a zerocics.config file in the CICS Dynamic Scripting installation's config directory. The contents of the installation config/zerocics.config file can be overridden by adding a config/zerocics.config file to your application's directory.
•	The slide contains examples of what goes in this file, but include the connection over which the CLI communicates to your CICS region, defaults for USERID and the tranid used for zero requests, plus any overrides for resources that are dynamically created.

N	lotes:
•	You can develop, debug, and test your applications in a variety of locations using a variety of development environments.
•	You can use text oriented editors such as ISPF, vi, or Notepad.
•	Eclipse plug-ins are available for editing and debugging Java, PHP, and Groovy code (see the CICS InfoCenter).
•	You can use RDz (Rational Developer for System z) or the Eclipse Target Management plug-in to edit files on your workstation that reside on z/OS USS (UNIX System Services). See the CICS InfoCenter for more details and a hyperlink to the plug-in.
•	In addition to an Eclipse environment or just using text editors, the AppBuilder is also available for developing on a workstation. The AppBuilder has a Web browser interface so you can use a Web browser to access a different machine that is running the AppBuilder code. The AppBuilder is not currently supported to run under CICS.
•	When developing on a workstation, you can create a modulegroup and associate it with your application. This ensures that during development you only add dependencies CICS allows. See the CICS InfoCenter on how to specify the modulegroup.
•	The CICS InfoCenter has a procedure for migrating a Dynamic Scripting application developed on your workstation to a CICS Dynamic Scripting environment.
•	Be careful editing files as most files are in UTF-8.

Ν	Notes:		
•	S H A R E Tentaty - Conduct - Tentaty While developing your CICS Dynamic Scripting application, there are certain concepts you will need to understand.		
•	You interact with your application for administrative purposes from a USS (UNIX System Services) command line. You will need to have a basic understanding of the available 'zero' commands. These commands allow you to create an application, start the application, stop the application, resolve application dependencies, and much more.		
•	The zero.config and zerocics.config were discussed previously, but you will need a basic understanding of the items in these configurations files that affect your environment, for example the port your application will listen on is set in the zero.config file.		
•	From a programming perspective you will need a basic understanding of the facilities that are available to your application:		
	 Events – your code, usually referred to as a handler, handles events in the Dynamic Scripting environment Global Context – can be accessed to find out information about your environment or temporarily store items PHP support – you can include PHP scripts in a Dynamic Scripting application 		
	Zero modules – various features available to your application are supplied in Zero modules		
	 Resolving dependencies – to include a feature, you specify that feature as a dependency Virtualized Directories – a way to look at your application's resources and all the resources it inherits Zero Resource Management (ZRM) – a way to work with data in a Zero environment REST support – Dynamic Scripting includes support for various aspects of REST 		
•	You will also need a basic understanding of how to interact with your CICS resources using the JCICS API.

	S H A R E Relating: Constant: Annual
•	Main Point: a Zero application is an event-based system.
•	All of the key behavior of the system is exposed to the application as a set of events, with the appropriate event state. Application developers mainly provide a set of handlers that hook into the well-known system events to achieve application behavior needed. The standard sMash events are meaningful activities of interest to applications.
•	Common events that most application developers use, like providing a response to a GET request to a URI or when an application is started, are provided. Event handlers are stateless blocks of function that handle the events. Events are identified by an event name, such as GET or LOG. Event handlers indicate an interest in handling a particular event under a particular condition.
•	Events in the Zero platform are ways to orchestrate behavior in the form of loosely-coupled event handlers. Zero "fires" a fixed set of events for HTTP request processing and stages of the application lifecycle; developers may add other event types. The application programming model is event based, so an event handler can be written in Groovy, PHP or Java, running in a browser or on the server side.
•	 "Firing" an event, which equates to an <u>API invocation</u>, causes Zero to invoke the associated handlers through an EventDispatcher. The set of associated handlers is determined by two mechanisms: Explicit registration: Evaluate registration rules. Implicit registration: Identify scripts as handlers through convention.

http://example.com/resources/people		Retrieve person	onRetrieve()
http://example.com/resources/people http://example.com/resources/people/john	GET	rectileve person	UNKELT TEVE()
· · · ·	GET PUT	Update person	onUpdate()
http://example.com/resources/people/john			

	Notes:
•	Let's take a look at how a RESTful service can be implemented using the Project Zero programming model.
•	Each PHP or Groovy script placed in the /app/resources directory of a Project Zero application is automatically treated by the platform as a RESTful handler for a category of resources, or a "resource collection". The name of the script represents the name of the collection. This script contains the logic to execute when processing inbound HTTP requests for that resource, separated into functions with well- defined names. The function that is invoked depends on the URI and HTTP method of the inbound HTTP request.
•	The URI pattern shown in the slide is a convention used to identify which collection to access based on the URI of an inbound HTTP request. If the URI contains just a collection name, the operation is targeted at the whole collection. If a member ID is specified in the URI after the collection name, the operation is targeted at an individual member of the resource collection. Optionally, additional information can be specified after the member ID.
•	This table shows an example with a resource collection called "people". The URI column shows two different kind URIs that can be used to interact with instances of the resource: the collection URI, which ends with the collection name - in this case "people", and the member URI in which an identifier for an individual person is specified - in this case, the name "john". We can see how a request URI, combined with an HTTP method, triggers an event such as List, Create, Retrieve, Update or Delete. These events are sometimes referred to as "L-CRUD" events. By convention, the Project Zero platform searches for handlers for these events a cript called "people.grovy" or "people.php" in the /app/resources directory. If this script provides an implementation of the function corresponding the the event, that function is invoked to handle the request.
•	Therefore, you can develop a RESTful service simply by creating a single script and implementing the subset of L-CRUD functions that you need. The platform takes take care of mapping inbound requests to your logic, by following a set of RESTful conventions.
