

Planning and Implementing NPIV For System z

Session 9479

Dr. Steve Guendert, Brocade Communications
sguender@brocade.com

Agenda

- Introduction
- NPIV background
- FCP Channels on the mainframe
- NPIV Planning
- NPIV implementation and configuration

Node Port ID Virtualization (NPIV)

Basics and background on NPIV and System z

zSeries/System z server virtualization

- zSeries/System z support of zLinux
 - Mainframe expanded to address open system applications
 - Linux promoted as alternative to Unix
 - Mainframe operating system virtualization benefits
 - Availability, serviceability, scalability, flexibility
- Initial zSeries limits
 - FCP requests are serialized by the operating system
 - FCP header does not provide image address
 - FICON SB2 header provides additional addressing
 - Channel ports are underutilized

FCP channel/device sharing-summary

- Different host operating systems sharing access to a single FCP channel may access the same fibre channel port via this channel.
- While multiple operating systems can concurrently access the same remote fibre channel port via a single FCP channel, fibre channel devices (identified by their LUNs) can only be serially re-used.
- In order for two or more unique operating system instances to share concurrent access to a single fibre channel or SCSI device (LUN), each of these operating systems must access this device through a different FCP channel.
- Should two or more unique operating system instances attempt to share concurrent access to a single fibre channel or SCSI device (LUN) over the same FCP channel, a LUN sharing conflict will occur, resulting in errors.

Consolidation

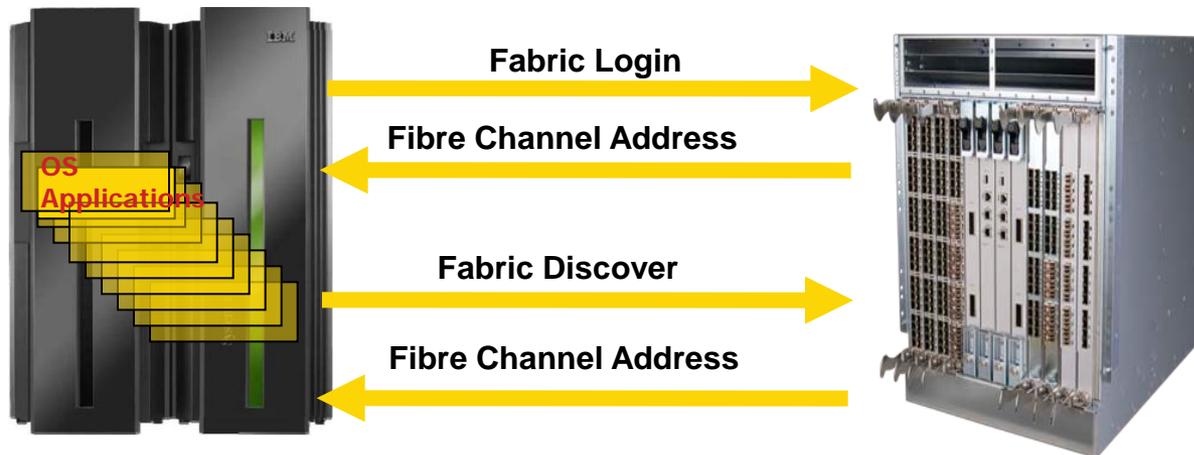

- Server consolidation
 - TCO compelling
 - IBM Project Big Green
- I/O consolidation
 - Resulting cost/performance benefit is not competitive

Node Port ID Virtualization (NPIV)

- Allows each operating system sharing an FCP channel to be assigned a unique virtual world wide port name (WWPN).
 - Used for both device level access control in a storage controller (LUN masking) and for switch level access control on a fibre channel director/switch (zoning).
- A single, physical FCP channel can be assigned to multiple WWPNs and appear as multiple channels to the external storage network.
- The virtualized FC Node Port IDs allow a physical fibre channel port to appear as multiple, distinct ports.
 - IO transactions are separately identified, managed, transmitted, and processed just as if each OS image had its own unique physical N port.

Server Consolidation-NPIV

- N_Port Identifier Virtualization (NPIV)
 - Mainframe world: unique to System z9 and later
 - zLinux on System z9/10/196 in an LPAR
 - Guest of z/VM v 4.4, 5.1 and later
 - N_Port becomes virtualized
 - Supports multiple images behind a single N_Port
 - N_Port requests more than one FCID
 - FLOGI provides first address
 - FDISC provides additional addresses
 - All FCID's associated with one physical port

Using ELS to assign N_Port IDs

- FC standard defines a set of services used to establish communications parameters, each of which is called an *extended link service* (ELS).
- An ELS consists of a request sent by an N_Port and a response returned by a recipient port.
- One ELS, called a *fabric login* (FLOGI), is sent from an N_Port to its attached fabric port (F_Port) in the adjacent switch to request the assignment of an N_Port ID.

Using ELS to assign N_Port IDs: FLOGI

- The FLOGI request is the first frame sent from an N_Port to its adjacent switch.
- The purpose of the FLOGI ELS is to enable the switch and the N_Port to exchange initialization parameters
 - Includes unique identifiers known as *worldwide port names* (WWPNs)
 - Allows the fabric to assign an N_Port ID to the N_Port.
- The switch responds with the N_Port assigned to the requesting N_Port.
- Because the N_Port that sends the FLOGI request does not yet have an N_Port ID, it sets the S_ID in the FLOGI request to zero.
 - The switch responds with a FLOGI-accept response that contains the assigned N_Port ID.
 - The “HBA” uses this assigned N_Port ID as the S_ID when sending subsequent frames.

Need to request multiple N_Port IDs: FDISC

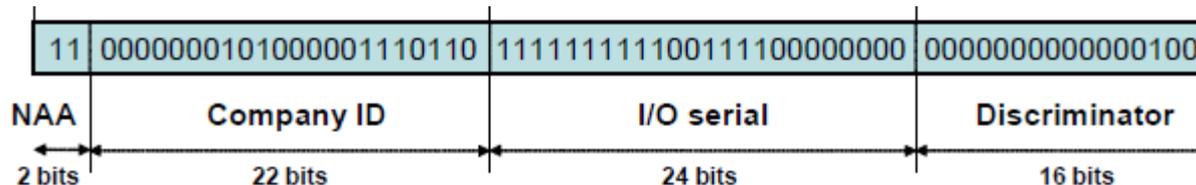

- Fabric Discovery (FDISC) is another ELS
- Original purpose is to verify an existing login with the fabric is still valid.
- The FDISC was always sent with a non-zero S_ID (the presumed S_ID of the sender).
- This made it possible to obtain additional N_Port IDs by an extension of the FDISC ELS.
- An unlimited number of additional N_Port IDs could be obtained

Without NPIV.....

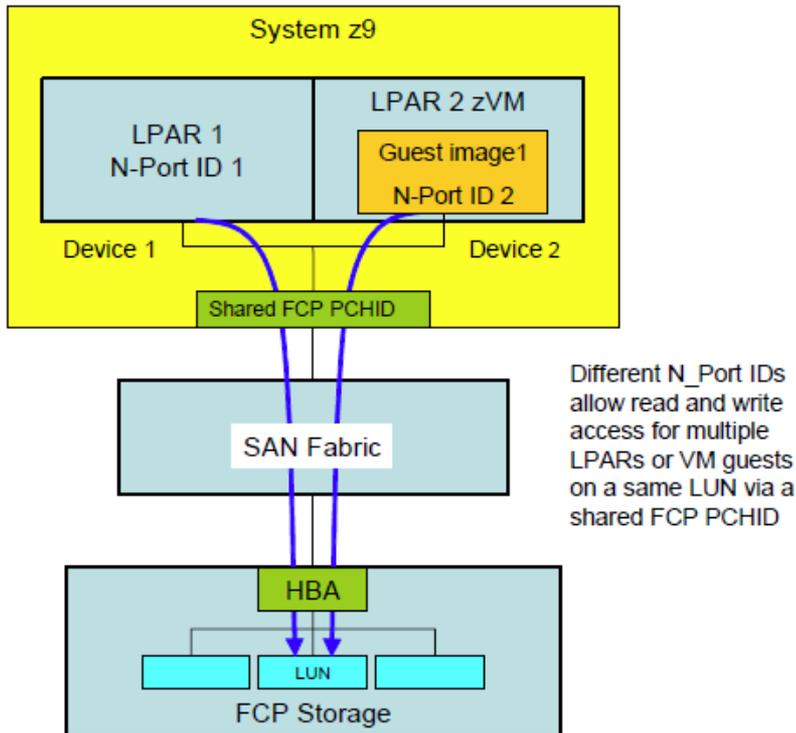

- Each operating system image that has an FCP port is identified to the fabric by the permanent WWPN of the port.
 - All OS images then have the same access rights within the fabric.
- The permanent WWPN of the port determines:
 - Zone membership for all images sharing the port.
 - Logical Unit Number (LUN) access rights for all images sharing the port.

With NPIV.....

- The Service Element (SE) creates new WWPNs for the FCP port at FLOGI.
- A unique WWPN is assigned to each OS image sharing the port.
- The generated NPIV WWPN is registered with the fabric switch.
 - This uniquely identifies each image for fabric zoning and LUN masking.
- For increased address space with System z, the low order 7 bits of the I/O serial field are combined with the 16 bit discriminator field.
 - Increases address space to over 8000000 unique WWPNs for a single FCP port.

Example illustration

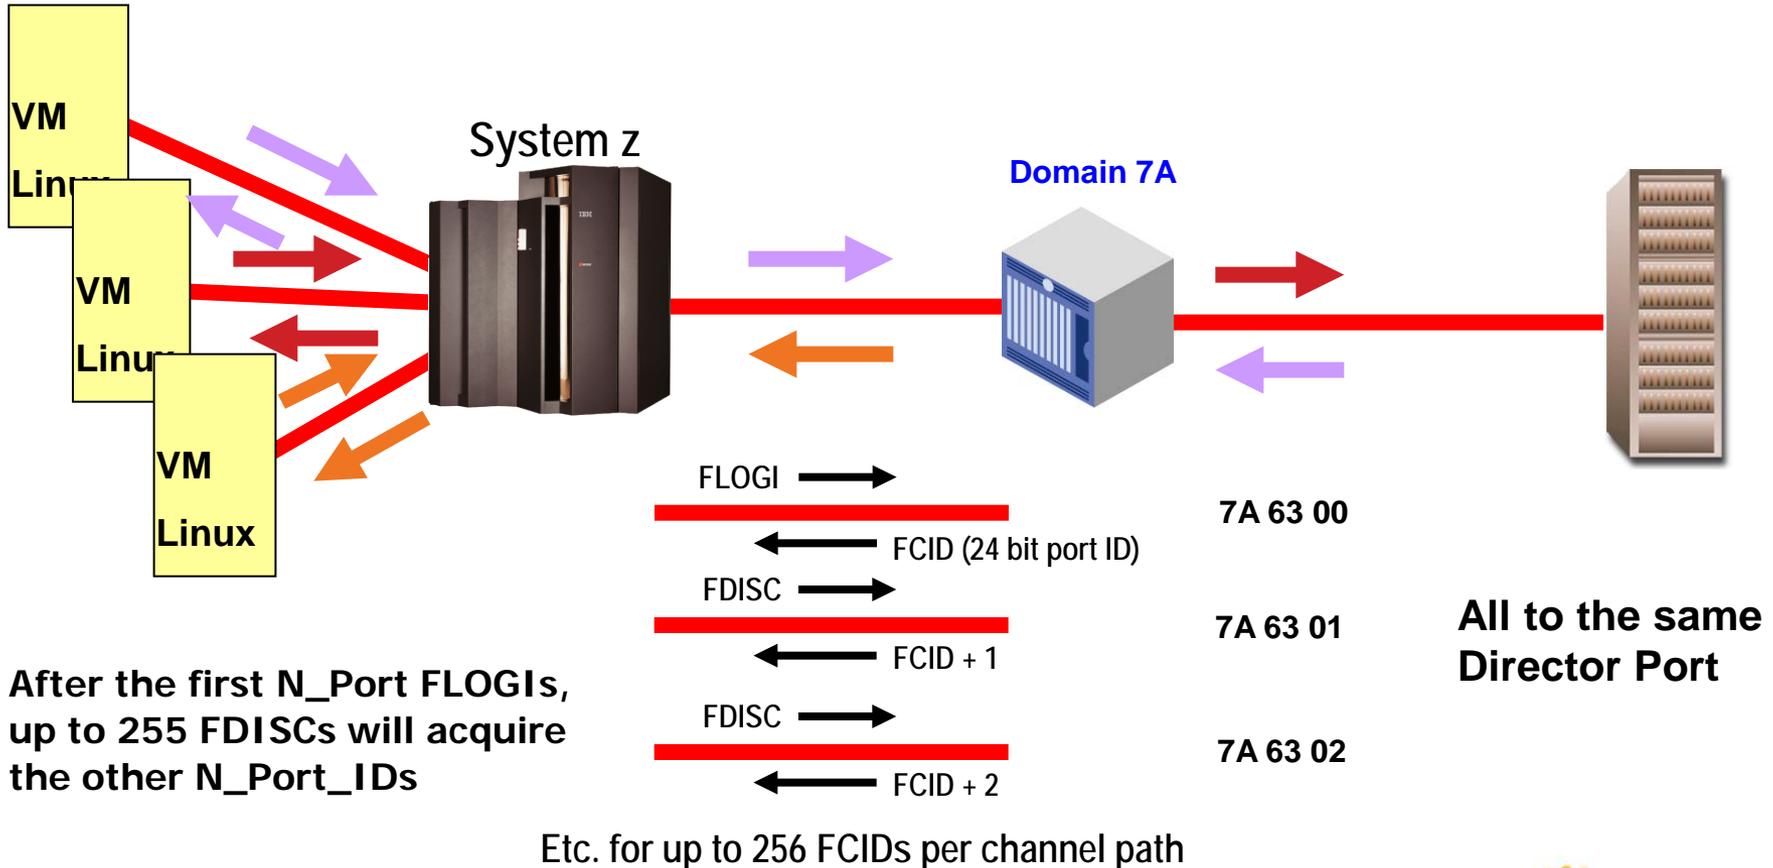

- In this figure, the two LPARs share a single physical FCP port.
- Each instance registers with the fabric's name server.
- The NPIV WWPN is supported in the FDISC process.
- Each LPAR receives a different N_Port ID to allow multiple LPARs or VM guests to read and write to the same LUN using the same physical port.
 - Without NPIV, writing to the same LUN over a shared port is not allowed.

System z N-port ID Virtualization-summary

One System z server port can have up to 255 NP-IDs
•IBM has told us it wants this expandable to thousands

- NPIV on the System z
- FCP Driver for System z
- Same CHPIDs as used for FICON

After the first N_Port FLOGIs,
up to 255 FDISCs will acquire
the other N_Port_IDs

FCP channels on the mainframe

FICON and FCP Mode

- A FICON channel in Fibre Channel Protocol mode (CHPID type FCP) can access FCP devices through a single Fibre Channel switch or multiple switches to a SCSI device
- The FCP support enables z/VM, z/VSE, and Linux on System z to access industry-standard SCSI devices. For disk applications, these FCP storage devices use Fixed Block (512-byte) sectors instead of Extended Count Key Data (ECKD) format.
- FICON Express8, FICON Express4, FICON Express2, and FICON Express channels in FCP mode provide full fabric attachment of SCSI devices to the operating system images, using the Fibre Channel Protocol, and provide point-to-point attachment of SCSI devices.

FICON and FCP Mode (Continued)

- The FCP channel full fabric support enables switches and directors to be supported between the System z server and SCSI device, which means many “hops” through a storage area network (SAN).
- FICON channels in FCP mode use the Queued Direct Input/Output (QDIO) architecture for communication with the operating system.

FCP channel and device sharing

- An FCP channel can be shared between multiple Linux operating systems, each running in a logical partition or as a guest operating system under z/VM.
- To access the FCP channel, each operating system needs its own QDIO queue pair defined as a data device on an FCP channel in the HCD/IOCP.
- These devices are internal software constructs and have no relation to physical devices outside of the adapter.
- These QDIO devices are also referred to as subchannels.

FCP channel and device sharing

- An FCP channel can be shared between multiple Linux operating systems, each running in a logical partition or as a guest operating system under z/VM.
- To access the FCP channel, each operating system needs its own QDIO queue pair defined as a data device on an FCP channel in the HCD/IOCP.
- These devices are internal software constructs and have no relation to physical devices outside of the adapter.
- These QDIO devices are also referred to as subchannels.
- The host operating system uses these subchannels as vehicles to establish conduits to the FCP environment.
- Each subchannel represents a virtual FCP adapter that can be assigned to an operating system running either natively in an LPAR or as a guest OS under z/VM.

NPIV PLANNING AND IMPLEMENTATION

Best practices and good ideas

Planning guide

- Good reference material available from IBM Redbooks
- 2005 Redbook
 - Z9
 - 6064
 - 2 Gbps

NEWS FLASH !!!

- An update to the 2005 Redpaper is going to happen
- Joint paper (IBM-Brocade)
- Reflection of:
 - New mainframe technology (zEnterprise)
 - Improved channel technology (FICON Express 8S)
 - Improved switching technology

General planning considerations

- Do not use more than 32 subchannels per physical channel in NPIV mode.
- Do not use more than 128 total target logins per physical channel in NPIV mode.
 - Example: in a configuration with 32 subchannels limit the target logins to no more than an average of 4.
- Using more subchannels, target logins, or both can cause timeout errors.

Using NPIV in the Real World

- IBM's 2005 guidelines recommend that a customer deploy no more than *32 virtual nodes per port-pair link* because of potential timeout issues
 - This is based on numbers that came with the 2005 2Gb environment
- There is a desire to move beyond 32 NPIV definitions per port, but the limiting factor is not the per port limit, but the fabric limit:
- Consequently, the 32 virtual links per physical link limitation is due to fabric and switch support limitations, which is a function of both memory resources and processing – which will get better over time
- The bigger problem is the name server size explosion, which is something that we will have to address before NPIV can be fully exploited to its maximum potential.

General planning considerations (2)

- Zone each NPIV WWPN individually.
 - Reduces fabric traffic since all participants in a zone would be notified when another N_Port joins/leaves the fabric.
- Consider using multipathing.
 - For details, please refer to the Redbook *Linux on zSeries: Fibre Channel Protocol Implementation Guide* (SG24-6344).
- Enable NPIV on the SAN switch/director prior to enabling it on the mainframe.
 - If NPIV is not enabled on the switching device first, the attempt to establish a connection to the fabric will fail for all subchannels that are operated in NPIV mode.

General planning considerations (3)

- Switching devices typically limit the number of supported N_Port IDs.
 - Because each NPIV WWPN is assigned an N_Port ID at login, this limit can be exceeded.
- Some switching devices also will limit the number of N_Port IDs that can be assigned to a physical port.
 - This limit varies by vendor/model
 - This limit also may be configurable on some switching devices.

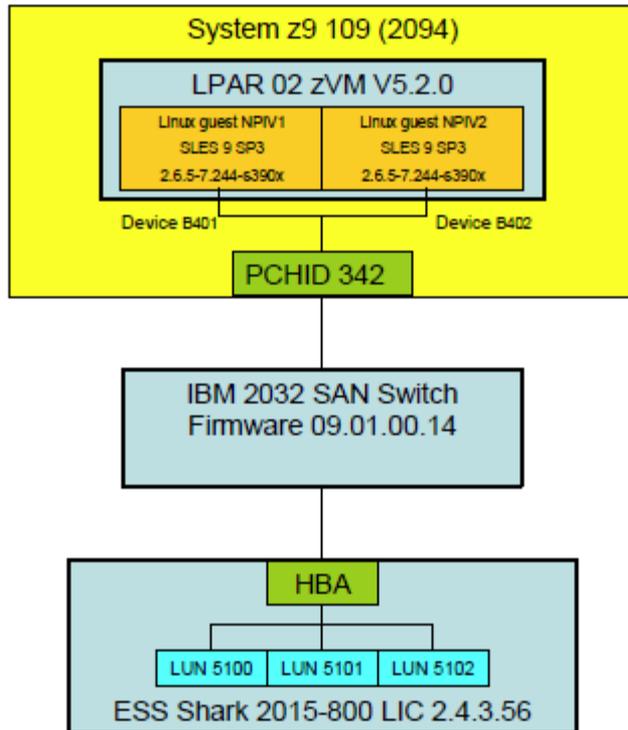

General planning considerations (4)

- Each login from an NPIV mode subchannel into a storage subsystem counts as a separate host login.
- Consult with your storage vendor for the specific limits in your configuration.
- Example:
 - IBM ESS model 800 supports up to 16 Host Bus Adapters (HBAs).
 - Each HBA supports up to 124 host logins
 - ESS 800 itself supports up to 512 host logins

Configuration section

- Section has many screen shots/captures
- 20 slides, but they will go by fairly quickly
- Some of the graphics used are from IBM software, Brocade management software, and/or illustrations from some of the references cited at the end of the presentation.

Configuration of NPIV

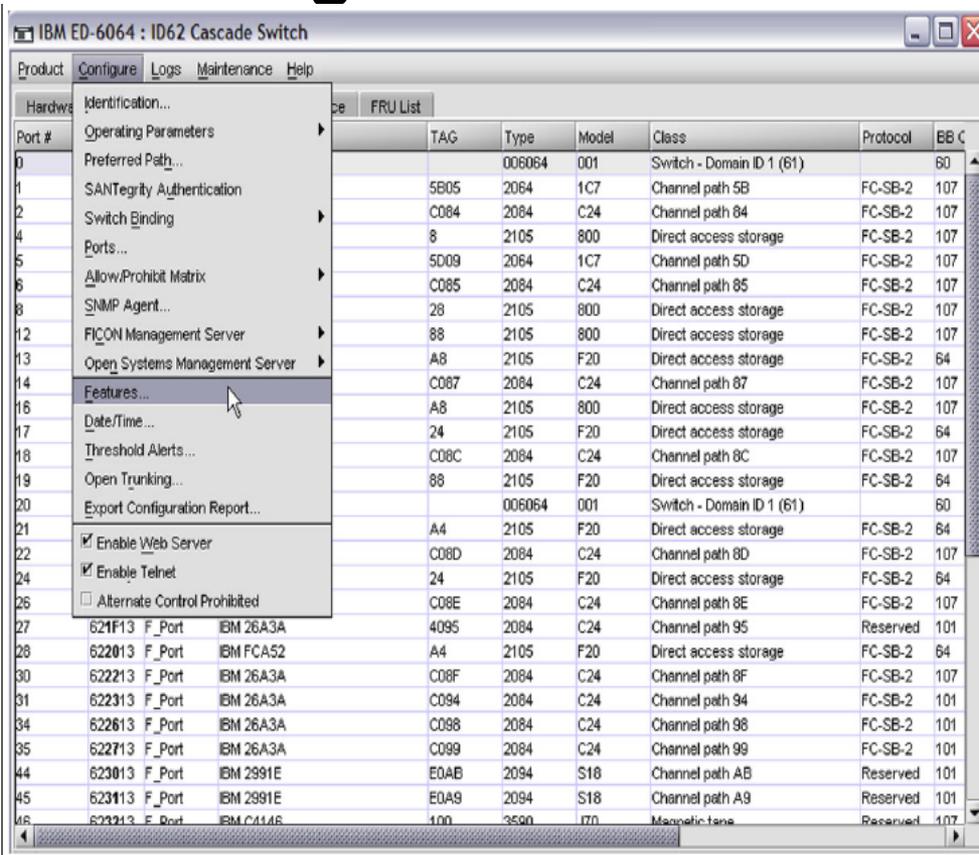

- Next several slides will walk through configuration steps.
- Configure:
 - NPIV on the switching device
 - NPIV on the mainframe
 - Fabric Security
 - Linux server
- For more specific details, please see references listed at end.

Configuring NPIV on the switching device

- Example of a specific switch, check your model's documentation for details on your switches.
- First, enable NPIV on the switch.
 - Add the NPIV feature key (if required)
 - Activate the NPIV feature
 - Configure NPIV on a specific switch port

Adding NPIV feature to switch

Configuring NPIV on the mainframe

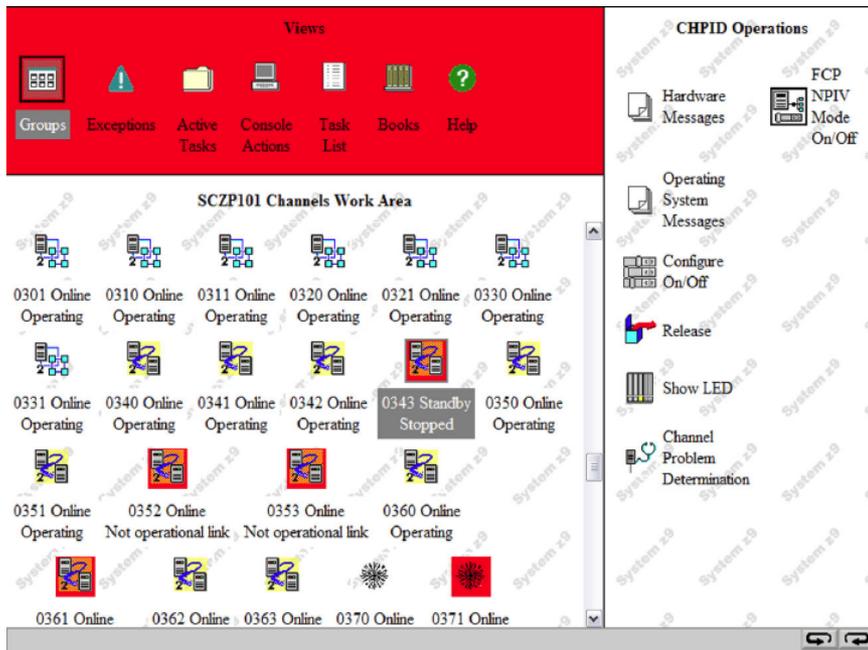

- Example we use is a System z9
- Configure NPIV on the switch first
 - If NPIV is enabled on our System z9 but not on the switch, the FCP CHPID reverts to non-NPIV mode on Fabric Login.
 - A CHPID off/on will then be required to enable NPIV once the switch has NPIV configured/enabled. (Disruptive)
- To enable NPIV, we will
 - Enable the NPIV feature on the mainframe
 - Find the NPIV WWPNs for the FCP CHPID
 - Find the permanent WWPN for the FCP CHPID

Enabling the NPIV feature on our z9

- Can be enabled from the CHPID operations menu in the SE
- From the HMC, select the Single Object to navigate to the SE:
 - Select your CPC, right click, and select the **Channels** option.
 - Scroll over to the **CHPID Operations** task on the right.
- The NPIV feature can be selectively enabled for individual LPARs.
- From the **CHPID Operations** menu.....

Enabling the NPIV feature on our z9 (2)

Enabling the NPIV feature on our z9 (3)

The screenshot shows the SHARE management console interface. The top navigation bar includes 'Views' with options like Groups, Exceptions, Active Tasks, Console Actions, Task List, Books, and Help. The main area displays the 'SCZP101 Channels Work Area' with a grid of channel status icons. A right-hand pane shows 'CHPID Operations' with options like Hardware Messages, Operating System Messages, Configure On/Off, Release, Show LED, and Channel Problem Determination. The 'FCP NPIV Mode On/Off' option is selected. A dialog box titled 'NPIV Mode On/Off' is open, showing a table with columns for Partition, CSS, CHPID, and NPIV Mode Enabled. The 'Apply' button is highlighted.

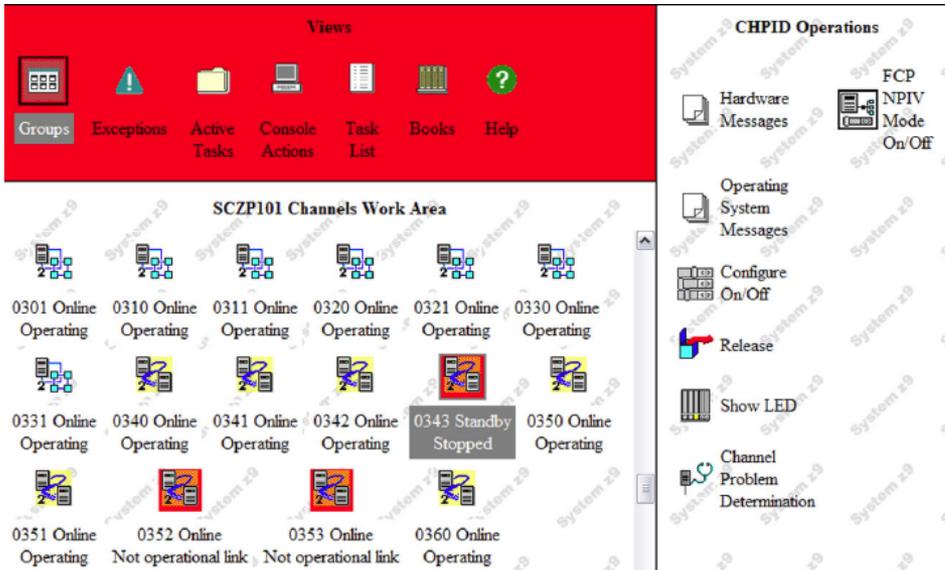

Partition	CSS	CHPID	NPIV Mode Enabled
A02	0	aa	<input checked="" type="checkbox"/>
A12	1	aa	<input type="checkbox"/>
A22	2	aa	<input type="checkbox"/>

- Select your PCHID number in the Channel Work Area
- From the **CHPID operations** menu on the right, double click **FCP NPIV Mode On/Off** to open the **NPIV mode on/off** menu
- Select the **NPIV Mode Enabled** option for each LPAR.
- Click **Apply** to commit the changes

Important note

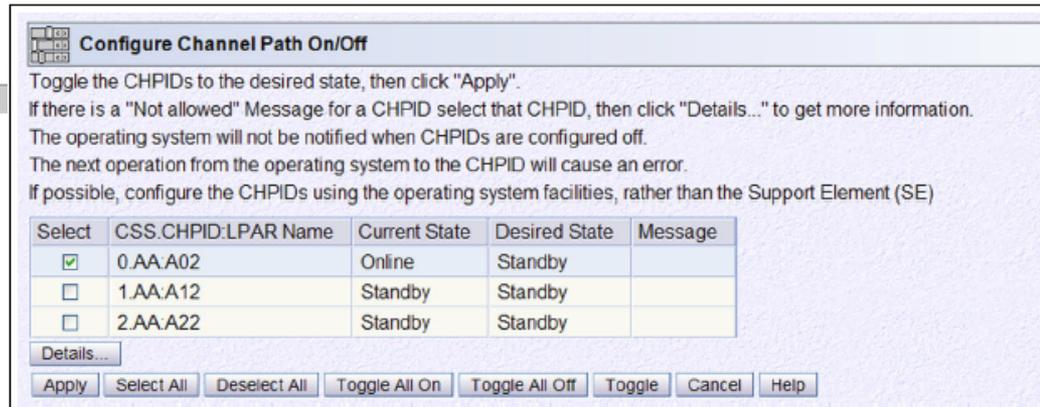

- To enable NPIV, the CHPID must be in standby state for the LPAR.
- If not, the **NPIV Mode On/Off** option is disabled to prevent any mode changes.

Setting the FCP CHPID online

The screenshot shows the main interface with a red top bar containing navigation icons for Groups, Exceptions, Active Tasks, Console Actions, Task List, Books, and Help. Below this is the 'SCZP101 Channels Work Area' displaying a grid of CHPID status icons. A right-hand pane titled 'CHPID Operations' is open, showing options like Hardware Messages, Operating System Messages, Configure On/Off, Release, Show LED, and Channel Problem Determination. The 'Configure On/Off' option is highlighted.

- **CHPID Operations Menu** -> double click **Configure Channel Path On/Off**
- Select the appropriate LPAR
- Click **Toggle** to change the **Desired State** option to **Online**
- Click **Apply** to commit the changes.

Configure Channel Path On/Off

Toggle the CHPIDs to the desired state, then click "Apply".
 If there is a "Not allowed" Message for a CHPID select that CHPID, then click "Details..." to get more information.
 The operating system will not be notified when CHPIDs are configured off.
 The next operation from the operating system to the CHPID will cause an error.
 If possible, configure the CHPIDs using the operating system facilities, rather than the Support Element (SE)

Select	CSS.CHPID:LPAR Name	Current State	Desired State	Message

Finding the NPIV WWPNs for the FCP CHPID

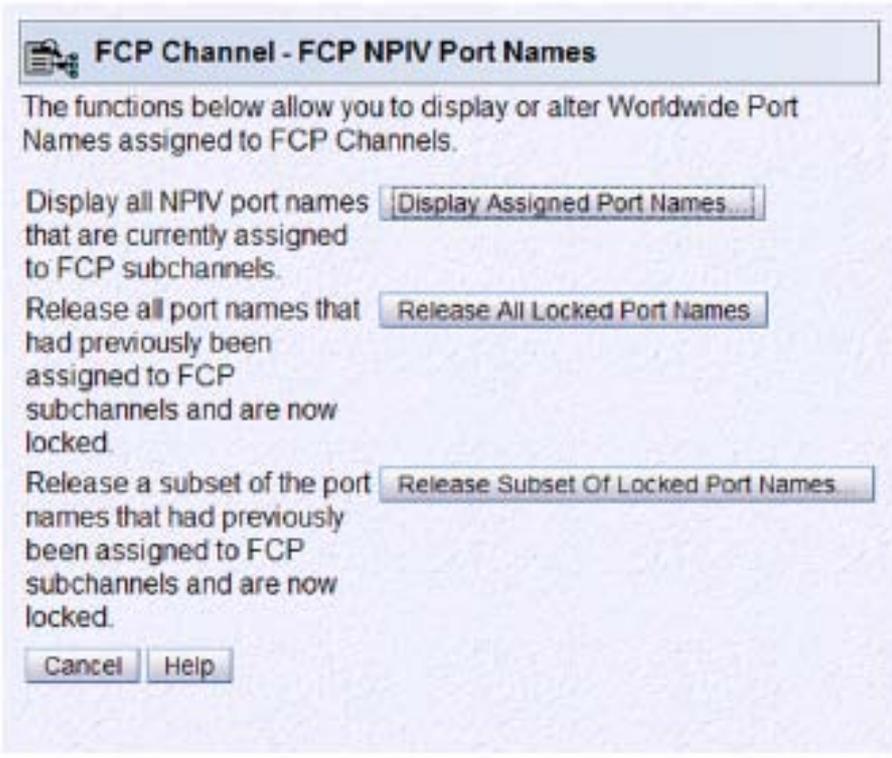

- Once we have enabled the NPIV mode, we can find the NPIV WWPNs assigned to an FCP CHPID.
- We need to know these WWPNs so we can:
 - Configure LUN masking
 - Configure zoning in the SAN
- We'll access the NPIV WWPNs from the CPC Configuration menu in the SE.

Finding the NPIV WWPNs for the FCP CHPID (2)

- Click **Display NPIV Configuration** to navigate to the **FCP channel –FCP NPIV Port Names** menu.

Finding the NPIV WWPNs for the FCP CHPID(3)

- Click **Display Assigned Port Name** to open the **Display Assigned Port Names Menu** (next slide).
- It's a good idea to restrict the number of WWPNs displayed by selecting the **Show NPIV=On** option.

Finding the NPIV WWPNs for the FCP CHPID(4)

Record the default WWPN (circled above in the screen shot)

Configuring Fabric Security

- The next step in the process is to define the NPIV and permanent WWPNs in the SAN fabric zoning and to the LUN masking on the DASD array.
- This configuration will be specific to the switch and array vendor/model.
 - Consult your vendor/model documentation for details on your specific requirements and steps.
 - *Linux on zSeries: Fibre Channel Protocol Implementation Guide* (SG24-6344) is an IBM Redbook that has a great general discussion on the subject of zoning and LUN masking.

Configuring Fabric Security-fabric zoning on the switching device

Configuring Fabric Security-LUN Masking

- LUN masking grants a WWPN or group of WWPNs access to a specific LUN.
- This is configured on the disk array management tool(s).
- Perform this task following configuration of zoning
- Wide variety of models, each is somewhat different.
- Consult vendor documentation

Configuring the Linux server

- We are now ready to configure the Linux server to use the NPIV WWPN.
- Each device on the FCP CHPID is assigned a unique WWPN.
- The WWPN used by a Linux server is determined by the FCP device of the server.
- 3 steps:

Configuring the Linux Server Step 1

- When running under z/VM, the FCP device must be attached to the virtual machine of the Linux guest.
- To attach dynamically, use the **CP Attach** command.

Configuring the Linux Server Step 1 (2)

- If the NPIV WWPN is unable to successfully login to the fabric, its WWPN is assigned the value 0x0000000000000000. Check zoning on the switching device.
- If an **“Out of resource in fabric”** message is shown, the reason might be that the **NPIV login limit** was set too small on the switch port.

```
