CICS Loader Domain

- CICS pre-ESA Loader
- CICS ESA Loader
- CICS TS Loader
- Loader Domain Control Blocks
- CICS TS 5.1 Loader
- Remaining Issues
- Wish List
- Questions

CICS pre-ESA Loader

- Used a pair of routines that were part of system initialization (DFHSIP). The two routine names were named: SIPBLDLE, and SILOADR
- MVS/ESA load was not used for 24-bit programs, instead a BPAM DCB was used to open the DFHRPL load library, and read it.
- SIPBLDLE did uses a MVS macro called BLDL to acquire the PDS member location, but discarded most of the returned information except TTRz, Length, AMODE, RMODE and entry point offset.
- The retained BLDL information was stored in the PPT itself, and was restored on a WARM or EMER restart.

CICS pre-ESA Loader issues

- CICS program subpool compressions or “Tree shakes” were nothing more than tossing out all programs with a current use count of 0, instead of using a Less Recently Used chain.
- Following the tree shake all the programs were slowly reloaded one at a time, on the QR TCB!
- ISV Software such as XA/Relo was a popular solution to eliminate the problem prior to CICS/ESA Loader redesign.

CICS ESA LOADER

- CICS ESA introduced the use of the MVS “directed Load” facility. Which reportedly uses CCW chaining information, to eliminate individual I/Os.
- This is an Authorized facility, as the invoker can tell MVS the location to load the program into.
- Reentrant DSA(s) introduced in CICS 3.3, allowing RENT programs to be loaded into non-fetch protected Key 0 storage.

CICS ESA LOADER

- In the new Loader domain design, a MVS/ESA BLDL macro was initially used to acquire the PDS directory information, later LLACOPY was added in TS 4.1, but still returns the BLDL information in the same format.
- The returned BLDL information is then stored in the CPE control block, not the APE! Only the 1ST x3C bytes of the returned BLDL information is retained of the x4C bytes.
- The “RO” TCB is used by the Loader Domain, but has many other users, such as SAF/RACF security calls!!!

Loader Domain Program Storage

- Currently there are 16 Loader domain program storage subpools, starting with LDENRS on the following page.
- The loader domain subpools get distilled down to only 6 DSAs (3 DSAs and 3 EDSAs)

Some Loader Domain Control Blocks

- APE Active Program Element
- CPE Current Program Element
- NIU Not In Use Active Program Element
- CSECTL CSECT List
- LDA Loader Domain Anchor area
- LCA Library Control Area
- PLIBE Program Library Element

Loader Domain Control Block Roles

- **APE** **Active** in Loader domain terms means it is occupying DSA storage, 2 chains: Storage Sequence and Not In Use sequence (or NIU) used during DSA/EDSA program subpool compressions
- **CPE** **Current** in Loader domain terms means it contains the current BLDL Information
- **CSECT** Lists are used by CICS Management modules to identify CSECTs within a Fat Load module
- **LDA** Anchor point or starting point for most Loader Domain storage chains
- **PLIBE** Program Library Entry – in ranking seq.
- **LCA** Library Control Area – in creation seq.

Relation of a PPTe to LD CPE and APE

- Every Program will have a CPE, but the APE is acquired the first time the program is referenced.
- A CPE can exist without a corresponding PPT entry, such as CICS management modules.
- One more APEs are chained from the CPE entry, and is normally one 1 to 1 relationship, unless a New Copy Phase-in was used on an active program.

What is the purpose of a CPE ?

```

CICS TS Loader

- CICS TS 3.2 added the concept of “Libraries”.
- Each Library uses 624 bytes of 24-bit storage for the LCA, forced below because it contains a z/OS DCB and BLDL parmlist.
- Each Library defined has a PLIBE area and an Library control area or LCA
- The following pages show what they look like:

CICS TS Loader LCA & DCB

CICS TS Loader

- Misuse of Libraries can be detrimental to performance!
See example of LD trace at: <http://tinyurl.com/LD-Trace>
- Around CICS TS 4.1 time Loader TCB bottlenecks started to reappear in higher transaction rate CICS systems, and could impact SAF performance!
- Vendors that open their own DFHRPL DCB will have problems!
- Is it a good idea to put all vendor programs in Library(s) and leave the DFHRPL for CICS and IBM Load Libraries?

CICS TS 5.1 Loader

- The CICS TS Loader has been improved in TS v5.1 to move all the CPE, APE and CSECT List control blocks into 64-bit addressable storage (31-bit VSCR)
- New CPE Chain added from the Library Resource (PLIBE) to keep track of all programs loaded from that Library. This is done for support of Application Bundles.
- Another major improvement to the loader domain was that LOAD requests for Threadsafe tasks no longer have to switch to the Loader “RO” TCB. LLACOPY and BLDL still use the RO TCB
- CPE in TS 5.1 is 240 bytes, APE in TS 5.1 is 192 bytes. A CPE with a single APE occupies 432 bytes per program.
- Moving 10,000 to 64-bit storage is roughly 4Meg of EDSA

CICS Loader Domain Anchor Area

Impact of CICS TS 5.1 Loader changes

- Loader domain CPE chains are now 64-bit addresses!
(CPE_NEXT, CPE_PRIOR)
- Loader domain APE chains are now 64-bit addresses!
(APE_NEXT, APE_PRIOR, APE_OLDER_APE, APE_YOUNGER_APE, APE_OLDER_APE_NIU, APE_YOUNGER_APE_NIU)
- The PPTTE loader domain token address, is now 64-bit !
(PPTTE_LOADER_TOKEN) points to the Loader Domain's corresponding 64-bit CPE entry

PPT Pointer Change, and EXT.

Remaining Topics

- Order of magnitude improvement in the Loader domain for Threadsafe tasks, which can load their own programs without Queuing up on the Loader TCB.
- Are the bulk of your tasks still on the QR TCB? If so, this enhancement may not help you!
- The single RO or Loader TCB is still used for: SAF calls, BLDLs, LLACOPYs, NEWCOPYs, PHASEINs and QR task LOADs!
- Are your Loader Domain Global user exits: XLDLOAD and XLDELETE Threadsafe, so they can be driven on Multiple TCBs ?

Remaining Issues

- Sequential search using BLDL or LLACOPY on a series of Libraries, even if they are defined after the DFHRPL search order can significantly impact an already over taxed Loader TCB!
- Customer had a cool idea to put each vendor Load library in a separate CICS LIBRARY definition, and leave DFHRPL for CICS, LE, and their application programs. They called to ask why this would make our PLTPI time startup process so slow, on COLD starts? From a CICS Trace we could see we our Load Library, was 50th in the ranking List! So each of our 30+ programs we load at PLTPI time had to do 50 BLDL or LLACOPY requests before finding the program !!

Wish List

- Move the 16K of Library Control Area (LCA) indexes to
- 31-bit storage

- Create a new TCB for SAF/RACF requests, that is separate from the Loader TCB

- Option when defining a “Library” resource via CEDA or RDO to indicate you want a separate TCB for this Library.

- RDO Program entry to allow the specification of a single Library definition.

CICS TS 255 LSR Pools

- Local Shared Resources
- Threadsafe impact on LSR pools
- Control interval sizes
- Remaining Issues
- Wish List
- Questions

Local Shared Resources

- Tuning a moving target
- DBA tunes CI sizes
- Index levels increase
- Index records increase
- Some type of Automatic setting needed

Threadsafe impact on LSR pools

- Some of the threadsafe file control code needs to be serialized, this is done by using a new LSR pool lock.
- For years sharing was a good idea, now we need to rethink this for threadsafe applications, to avoid lock contention between different application files in the LSR pool! For example Is an open order file in the same LSR pool as payroll file?

Remaining Issues

- LSR Buffers remain 31-bit, can impact transaction rates due to EDSA compressions
- Odd Control Interval sizes can cause round up, and wasted virtual and real storage.

Wish List

- CICS needs to support all Control interval sizes supported by the VSAM BLDVRP macro, to avoid wasted space!
- Move LSR Buffers to 64-bit storage, to free up EDSA
- After the investment made in VSAM RLS, is IBM even willing to reinvest in going back to add 64-bit buffers into older code set containing LSR pools?

Wish List

- Allow CICS to pick a LSR pool dynamically, for example in the range of 100 to 200
- Allow specification of # of strings, and let CICS select index and data buffers based on a Minimum, Maximum, or average specification. CICS would then access a bit more information from the VSAM catalog, so calculate the number of High level index records for example. The number of strings plus High level index records becomes the average setting. Maximum would be the total # or index records.
- Come to Boston Share for my update on this topic!
