Customers Speak

"Our company's current IT management "wisdom" seems to believe that Microsoft is the answer (...) Because we don't have a .NET way to access IMS DB, most of our agencies seem to be doing IMS DB extracts and loading the data into Sql Server, Access, etc. This process gives management an additional excuse to move off the mainframe (...) There are solutions that would definitely solve the problem, unfortunately they are very expensive (...) So.. long story short, we need a .NET solution to IMS DB (both on/offline) yesterday"

- IMS Customer

Customer Requirements

- IMS DBMS customers want to be able to access IMS data directly from .NET applications using SQL
- Today, .NET-based IMS customers who need access to IMS data from .NET applications are forced to:
 - × Set up a replication environment where IMS data is copied to a .NET accessible database server
 - × Implement data proxy solutions that don't offer direct connectivity
 - × Increase code path by implementing bridge solutions
 - × Use expensive 3rd party products
- All of these alternate paths mean either higher development costs, higher management costs, and/or higher runtime costs

Introducing

IBM IMS Data Provider for Microsoft .NET

- IBM IMS Data Provider for Microsoft .NET
 - a component of IMS Enterprise Suite
- This product enables standard ADO.NET SQL access to IMS data from .NET applications in a simple, fast, well proven way
 - •Develop and reuse .NET applications (written in any .NET language, e.g. C#, VB, VC++) to access IMS data
 - •Perform CRUD operations via SQL directly against IMS data
 - •No need for intermediate steps/tools (such as DB2 stored procedures, web services, or 3rd party products) to access IMS databases from .NET

Microsoft ADO.NET and Data Providers

- Microsoft's development platform for Windows is known as the .NET Framework
 - Supports over 40 different programming languages. The most popular are C# and Visual Basic.
- The .NET Framework provides data access support through ADO.NET
- Your applications use databases through what's known as a data provider
 - Various database products include their own .NET data providers

Overview of IMS Data Provider

- The IBM IMS Data Provider for Microsoft .NET is a high performance, managed ADO.NET data provider created specifically for IMS database systems
- Designed for direct data manipulation and fast access to data
- Leverages IMS Catalog and IMS SQL engine
- Implemented according to ADO.NET data provider API specification
 - Enables standard, reusable code

IBM IMS Data Provider for Microsoft .NET

IMS Data Provider Architecture

IMS SQL Support

- SQL Engine for COBOL and distributed applications (.NET/JDBC)
- Provides standard SQL keywords to easily access IMS data
 - ✓ SELECT, INSERT, UPDATE, DELETE
 - ✓ Uses Dynamic SQL programming model
 - ✓ Converts SQL statements to DLI calls
 - Supports a subset of SQL keywords that are currently supported by IMS Universal JDBC driver
- Uses database metadata in IMS Catalog
 - \checkmark No need to generate metadata for use in applications

Connecting to IMS

A database connection is established through the IMSConnection class:

1. Create a string that stores the connection parameters. Typical format:

```
Server=<ip address/hostname>:<port number>;
```

- Database=<PSB name>;
- Datastore=<Datastore value>;
- User ID=<userID>;
- Password=<password>;
- Connect Timeout=<Timeout value>;
- Pooling=<true or false>;
- Encryption=<true or false>;
- 2. Pass the connection string to the IMSConnection constructor. Example:

```
String connectString =
    "Server=12.34.56.78:5555;Database=SAMPLE";
IMSConnection conn = new IMSConnection(connectString);
```

3. Use the Open method to connect to the database identified in the connection string:

```
conn.Open();
```

```
C# Application Example (SELECT)
    Example.cs ×
        using IBM.Data.IMS;
        static void IMSReader()
        {
               // Use connection string to configure connection properties
               IMSConnection connection = new IMSConnection("Data source = MyIMS,5555;
                  Database = Insurance");
               // Establish connection to IMS database
               connection.Open();
               // Specify SQL guery in the IMSCommand object
               IMSCommand command = new IMSCommand("SELECT * FROM PCB01.CUSTOMERS",
                            connection);
               // Execute query via the DataReader object
               IMSDataReader reader = command.ExecuteReader();
               // Iterate through results and output on the screen
               while (reader.Read())
                  Console.WriteLine(reader.GetString(0));
               // Close the reader
               reader.Close();
               // Close the connection
               connection.Close();
         }
```

C# Application Example (INSERT)

```
Example.cs X
    using IBM.Data.IMS;
    static void IMSWriter()
    {
           // Use connection string to configure connection properties
           IMSConnection connection = new IMSConnection("Data source = MyIMS,5555;
              Database=Insurance");
           // Establish connection to IMS database
           connection.Open();
           // Specify SQL command in the IMSCommand object
           IMSCommand command = new IMSCommand("INSERT INTO PCB01.CUSTOMERS (NAME,
              POLICY) VALUES ('EVGENI', 1210050000)", connection);
           // Execute command, return number of rows affected
           int i = command.ExecuteNonQuery();
           // Close the connection
           connection.Close();
    }
```

INSERT, UPDATE and DELETE commands are used identically

Parameters

- Applications can reference IMS SQL data type values as SQL statement parameters
 - '?' is used as parameter marker
- The IMSParameter object is used to represent a parameter to be added to a IMSCommand object
 - When specifying the data type value for the parameter, the data type values available in the IBM.Data.IMS.IMSType namespace must be used

```
Example.cs X

String CommandText = "INSERT INTO PCB01.CUSTOMERS (NAME, POLICY) VALUES (?, ?)";
IMSCommand command = new IMSCommand(CommandText, conn);

// Create and prepare an SQL statement.
IMSParameter nameParam = new IMSParameter("NAME", IMSType.VARCHAR, 100);
IMSParameter policyParam = new IMSParameter("POLICY", IMSType.BIGINT);
nameParam.Value = "Evgeni Liakhovich";
policyParam.Value = 1210050000;
command.Parameters.Add(nameParam);
command.Parameters.Add(policyParam);
```

Transactions

• IMS Data provider supports Local Transactions

• IMSTransaction object is responsible for rolling back and committing database transactions

```
Example.cs X
   IMSCommand command = connection.CreateCommand();
   IMSTransaction transaction;
   // Start a local transaction.
   transaction = connection.BeginTransaction("SampleTransaction");
   command.Transaction = transaction;
   try
   {
       command.CommandText = "INSERT INTO REGION (ID, NAME) VALUES (100, 'Portland')";
       command.ExecuteNonQuery();
       command.CommandText = "INSERT INTO REGION (ID, NAME) VALUES (200, 'Vegas')";
       command.ExecuteNonQuery();
       transaction.Commit(); // Attempt to commit the transaction.
   catch (Exception ex)
       transaction.Rollback(); // Attempt to roll back the transaction.
```

Generic Coding

- .NET Framework outlines the "generic coding", or "factory-based" interfactors inter
 - Facilitates generic ADO.NET application development, constant programming interface across different databases
 - When using this technique, proprietary class names, such as IMSConnection, are replaced with common names, such as DbConnection

```
Example.cs ×

using IBM.Data.IMS;

static void GenericReader()
{
    DbProviderFactory factory = DbProviderFactories.GetFactory("IBM.Data.IMS");
    DbConnection connection = factory.CreateConnection();
    DbConnectionStringBuilder sb = factory.CreateConnectionStringBuilder();
    connection.ConnectionString = sb.ConnectionString;
    connection.Open();
    DbCommand command = new DbCommand("SELECT * FROM PCB.CUSTOMERS", connection);
    DbDataReader reader = command.ExecuteReader();
```

Connection Pooling

- When a connection is first opened against an IMS database, a connection pool is created. As connections are closed, they enter the pool, ready to be reused.
- The IMS Data Provider enables connection pooling by default
 - Note: You can turn connection pooling off using the Pooling=false connection string keyword/value pair
- You can control the behavior of the connection pool by setting connection string keywords for the following:
 - The minimum and maximum pool size (MinPoolSize and MaxPoolSize)
 - The length of time a connection can be idle before it is returned to the pool (ConnectionLifetime)

Data Types

• Supported IMS data types and their .NET equivalents

IMS Type	.NET Type	Method				
TINYINT	Byte	GetByte				
SMALLINT / INTEGER / BIGINT	Int16 / Int32 / Int64	GetInt16/GetInt32/GetInt64				
DOUBLE / FLOAT	Double / Single	GetDouble / GetFloat				
BIT	Boolean	GetBoolean				
CHAR / VARCHAR	String	GetString				
PACKEDDECIMAL / ZONEDDECIMAL	Decimal	GetDecimal				
DATE / TIME / TIMESTAMP	DateTime	GetDateTime				
BINARY	Byte[]	GetBytes				

 No truncation or data loss occurs when using listed methods for corresponding data types. Other methods can often be used, however, data integrity cannot be ensured.

Reading Results

- Reading the result sets is done through a IMSDataReader object.
 Read() method is used to advance to the next row in the result set.
- The methods GetString(), GetInt32(), GetDecimal(), etc. are used to extract data from the individual columns
- Close() method is used to close the IMSDataReader object, which should always be done when reading the output is finished

```
txample.cs X

int row = 1;
while (reader.Read())
{
    //Print out Column Names if we are on the first row
    if (row == 1)
        for (int i = 0; i < reader.FieldCount; i++)
            Console.Write(reader.GetName(i) + "\t");
        Console.WriteLine();
        //Print out Column values converted to String
        for (int i = 0; i < reader.FieldCount; i++)
            Console.Write(reader.GetString(i) + "\t");
        row++;
    }
</pre>
```

Connected vs Disconnected Modes

- IMS Data Provider will support both Connected and Disconnected data access modes
 - The connected mode uses DataReader class and allows direct data manipulation and fast, forward-only, read-only access to data
 - IMS Data Provider also serves as a bridge between a data source and an ADO.NET DataSet interface
 - The DataSet object is central to supporting disconnected, data scenarios with ADO.NET
 - The DataSet is a memory-resident representation of data that provides a consistent relational programming model regardless of the data source
 - The **disconnected** architecture allows fetching data from IMS into a DataSet, manipulating data without holding database locks, and committing all changes at once to IMS when all work is finished

Choosing between DataReader and DataSet

- Consider the type of functionality that your application requires. Use a DataSet to do the following:
 - Cache data locally in your application so that you can manipulate it. If you only need to read the results of a query, the DataReader is the better choice.
 - Perform extensive processing on data without requiring an open connection to IMS, which frees the connection to be used by other clients.
 - Disconnected mode uses optimistic concurrency, good for environments with low data contention
- If you do not require the functionality provided by the DataSet, you can improve the performance of your application by using the DataReader to return your data in a forward-only, read-only manner.

Processing Metadata

- Database Metadata (or Schema) will be used to describe design and specification of the data structures in the database
- IMS Data Provider will offer two ways to read and process IMS metadata:
 - GetSchemaTable() method of the IMSDataReader class result set level metadata
 - GetSchema() method of the IMSConnection class collections of metadata about the entire database

Protecting Your Data

- Encrypt your data (AT-TLS standard will be supported):
 - Configure AT-TLS on the host side
 - Generate server certificate
 - Install server certificate on the client machine
 - Connection String: Encrypt = true
- Encrypt Configuration Files
 - Store and encrypt connection strings in configuration files, instead of embedding them in your application's code
- RACF Authentication
 - Connection string: User ID=<userID>;

Password=<password>;

- Applies to rows as well as columns
 - IMSDataReader.Read assumes all columns will be Get'd
- Connections open late, close early
 - Maximize the use of connection pooling
- Other objects close / dispose, set reference to null
 - IMSDataReader.Close, IMSCommand.Dispose
 - Allows the server to free locks and clean up cursors earlier
- Set IMSCommand.FetchSize to optimize network performance
 - If the end user consumes a lot of data, you will want your application to minimize the number of round-trip data fetches
- Qualify IMS segment names with PCB names
 - For example PCB01.HOSPITAL

GUI / Web Development

- Visual Studio is a powerful environment for developing GUI and web applications
 - Interactive applications that work with IMS data are easy to develop

Available now

ibm.com/ims \rightarrow IMS Enterprise Suite

The IMS[™] Enterprise Suite is a set of components that support open integration technologies to enable new application development and extend access to IMS transactions and data. The IMS Enterprise Suite provides user-friendly standard interfaces, simplifies IMS metadata generation, and enables IMS business event data and monitoring. The IMS Enterprise Suite simplifies and expands IMS development (including Java[™] and XML), administration, and access. Graphical user interfaces and standards-based programming models are provided through tooling support from the WebSphere® and Rational® product families.

The IMS Enterprise Suite includes components that are available for both z/OS® and distributed platforms, and is a no-cost product for unlimited installs. The IMS Enterprise Suite components are designed to complement IMS 13, IMS 12 and IMS 11.

IMS Enterprise Suite Components

IMS Enterprise Suite Data Provider for Microsoft .NET enables you to use standard SQL queries to access IMS data from .NET applications. It delivers high-performing, secure access to IMS data and simplifies the development of Microsoft .NET applications (for example, C# and Visual Basic) that access IMS.

IMS Data Provider for Microsoft .NET installation

- Go to the IMS Enterprise Suite download site and log in.
- Select IMS Enterprise Suite Version 3.1 and click Continue.
- Select IMS Data Provider for Microsoft .NET and click Continue
 - IMS Data Provider for Microsoft .NET download page
- Select the IMS Data Provider for Microsoft .NET repository file
- Click **Download now** to download the selected files.
- Store the compressed repository file in a accessible location
- You must have IBM Installation Manager Version 1.5.3 or later installed

24

Getting Started

- Documentation:
 - http://publib.boulder.ibm.com/infocenter/dzichelp/v2r2/to pic/com.ibm.ims.net31.doc/net_intro.htm
 - "Verifying installation" page is a good place to start
- Look for getting_started.txt and a sample project in the installation directory after installing the .NET Data Provider
- Video tutorials and demos on YouTube:
 - <u>http://bit.ly/IMS_YouTube</u>

System Requirements

- Software requirements
 - IMS DB v13, APARs PM96324 and PI05437
 - IMS Connect, ODBM
 - Catalog
 - .NET Framework 4.0
 - Windows XP, Windows 7
- Hardware requirements
 - For IMS DB same as IMS v13
 - For .NET Data Provider and Visual Studio
 - Computer that has a 1.6GHz or faster processor
 - 1 GB (32 Bit) or 2 GB (64 Bit) RAM (Add 512 MB if running in a virtual machine)
 - 3GB of available hard disk space
- Tooling
 - Microsoft Visual Studio

Thank You! Your Feedback is Important to Us
