Abstract and Agenda

- This session will provide information on how to use trace to solve problems, identify performance issues and profiling of CICS applications.
- Agenda:
 - Overview of trace options
 - Review of trace resources
 - A look at trace formats
 - Using trace for problem resolution
 - Using trace for performance management
 - Using trace for application profiling

Overview of Trace Options

- Standard Trace
 - STNTR=OFF – Turn off all of trace
 - STNTREI=(1,2) – EXEC Interface
 - STNTRLD=(1) – LD domain
 - STNTRME=(1,2) – ME domain
 - STNTRNQ=(1,2) – NQ domain
 - STNTRRI=(1) – Res Mgr interface
 - STNTRRM=(1,2) – RM domain
 - STNTRRX=(1,2) – RX domain
 - STNTRSM=(1) – SM domain
 - STNTRXM=(1,2) – XM domain
- Special Trace
 - SPCTR=OFF – Turn off all of trace
 - SPCTREI=(1,2) – EXEC Interface
 - SPCTRLD=(1) – LD domain
 - SPCTRME=(1,2) – ME domain
 - SPCTRNRQ=(1,2) – NQ domain
 - SPCTRRI=(1) – Res Mgr interface
 - SPCTRMM=(1,2) – RM domain
 - SPCTRXX=(1,2) – RX domain
 - SPCTRSW=(1) – SM domain
 - SPCTRXXM=(1,2) – XM domain

Complete your session evaluations online at www.SHARE.org/Seattle-Eval

5

Trace Levels:

Trace points of the latter type each have an associated "level" attribute. Trace levels could, in theory, range in value from 1 to 32, but in practice nearly all mainline trace points have a trace level of 1 or 2. **Level 1** trace points are designed to give enough diagnostic information to resolve "user" errors. These trace entries are produced for the following situations; at **ENTRY** to and **EXIT** from a Domain, at **ENTRY** to and **EXIT** from all major internal Domain functions, *Before* and *After* all calls (**EVENTS**) to other programs/subsystems, and usually at **ENTRY** to and **EXIT** from a component of the AP Domain. **Level 2** trace points are located between the level 1 trace points. They provide information that is likely to be more useful for resolving errors within CICS modules. Level 2 trace points normally would be used only if requested IBM support staff. **Level 3** trace points are well inside of CICS code and *are not documented*, normally IBM internal use only.

Trace Components:

Components are very finite within their implementation and provide tremendous flexibility in controlling the amount of trace output. The components shown on this slide represent the key domain trace activity which is best choice for problem solving with the least amount of trace overhead.

Trace Options:

Trace may also be controlled during CICS initialization through the use of **SIT** or **SIT overrides**. These allow for installation setting of specific standards, but may be changed via **CEMT** or **CETR** transactions; or by **EXEC CICS** commands. The major options are:

SYSTR – Controls the master system trace flag
STNTR – Global specification for standard tracing
TRTABSZ – Size (in kilobytes) of the internal trace table
AUXTR – Auxiliary Trace data sets are to be used
STNTRxx – Standard trace, component specification

USERTR – Controls the master User trace flag
SPCTR – Global specification for special tracing
GTFTR – MVS GTF is a destination for trace
AUXTRSW – Auxiliary trace autoswitch facility
SPCTRxx – Special trace, component specification

CETR Transaction			 SHARE Sharing... Learning... Growing...

		3/4/2015	6

CETR provides online control of the CICS trace facility and its activity. Once presented with the first (menu) screen, any of the input fields can be over-typed with the new values that you require. When ENTER is pressed, CETR issues the necessary commands to set the new values and their changes are recorded in the global and local catalogs. These new values will remain in effect until changed again or a *cold start* is performed.

There are two other main functions of CETR, as follows:

- Setting the component trace options
- Setting the transaction and terminal trace options.

The "Component Trace Options" display is produced by pressing PF4 on the main CETR display.

CETR Transaction		S H A R E Sharing - Learning - Growing

in Seattle 2015

The "Component Trace Options" display is produced by pressing PF4 on the main CETR display. PF7 and PF8 can be used to scroll backwards and forwards through the list of components. Values can be changed by overtyping and pressing ENTER.

The trace options for a particular component consist of two sets of 32 flags, which support the 32 possible levels. One set gives the active levels of tracing for STANDARD tracing tasks; the other set gives the levels for SPECIAL tracing tasks. The flags are represented as a list of numbers, **1 through 32**, separated by commas. Consecutive values in the list are shortened to a range notation, i.e. 1-3 is the same as 1,2,3. The special values **ALL** and **OFF** are used to represent "all flags on" and "no flags on" respectively.

Complete your session evaluations online at www.SHARE.org/Seattle-Eval 3/4/2015 9		

The "Transaction and Terminal Trace" display is produced by pressing PF5 on the main CETR display. It can be used to set STANDARD, SPECIAL, or SUPPRESSED tracing for particular CICS tasks. This is done by setting the appropriate value for the transaction ID used to start the task, or for the terminal from which the task is to be run. Note that **SUPPRESSED** cannot be set for terminals, only for transaction IDs. The required terminal can also be specified by using its Netname.

This display can also be used to enable VTAM exit tracing and ZCP trace for specified terminal IDs or netnames. There are also fields that allow enabling of all non terminal VTAM exits, and PF6 can be used to cancel all exit tracing.

This slide shows the utility to print auxiliary trace data. Most sites only have trace captured in memory in dumps. There are times when it might be best to record trace data to a data set.

The diagram shows the process of switching the data sets. From a terminal in CICS (or the console) you enter the transaction CEMT S AUX SW. As the diagram indicates CICS will switch trace data set usage. From data set A to B in this case. *Please be sure to make a note of the now active data set from the response.* You can now use the utility to print the desired dumps.

We have provided a sample set of JCL, although it is modified slightly from the IBM sample. The name of the program is version dependent, DFHTU690 is V5.2. If you have multiple versions just make sure the name matches the version. The rest of the JCL really has not changes for many years.

The DFHAXPT DD will supply the DSN of the trace data set to use. We have DDs for both data sets and just comment one out are required. The rest of the DDs are quite standard for print.

As for the DFHAXPRM statements, we only show the minimum of options. You will need to refer to the IBM documentation for all of the options. What we have here will get you started. The **SHORT** statement specifies that the shorter form of each trace entry should be printed. This will be two lines per entry. The **ABBREV** statement specifies that the abbreviated form of each trace entry should be printed. This will be only one line per entry. The **HULL** statement specifies that the complete form of each trace entry should be printed. This will many lines per entry, some can be a full page of print.

In a JCL comment we show two of the key selection parameters. The **EXCEPTION** specifies that only exception trace entries should be printed. The **TIMERG** specifies the range of time, in hours minutes and second, you want to print trace entries from.

CICS Trace Print Utility

- Parameters for the utility:
 - SHORT, ABBREV, or FULL
 - TRANID=(xxxx,yyyy) – one or more transaction codes
 - TERMID=(xxxx,yyyy) – one or more terminal identifiers
 - TASKID=(nnnnn,nnnnn) – one or more task numbers
 - KE_NUM=(xxxx,xxxx) – one or more KE entry hexadecimal values
 - ENTRY_NUM=(nnnnnn-nnnnnn) – specify a range of entry numbers
 - TIMERG=(hh:mm–hh:mm) – time range of trace entries
 - PAGESIZE=60 – specifies the number of lines on a page
 - UPPERCASE – specifies that output is to be upper case only
 - ALL (default) or EXCEPTION or TYPETR=(ddxxxx,ddxxxx-xxxx)
- Required is one of SHORT, ABBREV, and FULL (default)
- Selection options may refer to a single value, multiple values, or a range of values

Complete your session evaluations online at www.SHARE.org/Seattle-Eval

11

ABBREV|SHORT|FULL

Specifies how much of each trace entry you want printed. If you specify this statement, it must always be the first statement in either the PARM parameter or the DFHAXPRM data set.

ABBREV – Indicates that you require the abbreviated, one-line-per-entry, form of trace print.

SHORT – Indicates that you require the short formatted print of the data in each entry. This consists of the information in the abbreviated format entry, and the following elements from the interpretation string of the fully formatted entry; interpreted parameter list, Return address, Time, and Interval.

FULL – Indicates that you want a fully formatted print of all the data in each entry, (default value).

TRANID=(tttt[,tttt,...,]) - This statement specifies the transaction identifiers of one or more transactions for which trace entries are to be printed.

TERMID=(tttt[,tttt,...,]) - This statement specifies the terminal identifiers (tttt) of one or more terminals for which trace entries are to be printed.

TASKID={({id|id-id},.,{id|id-id},...}) - This statement specifies the task identifiers (id) of one or more tasks for which trace entries are to be printed. An id value can be any number up to five decimal digits long, any of the character strings JAS, J01 through J99, III, TCP, or DSTCB, or any non-numeric two-character domain ID of the attaching domain.

KE_NUM=(xxxx[,xxxx,...]) - This statement specifies that only the entries for tasks with the specified hexadecimal kernel task numbers are printed.

ENTRY_NUM={({nnnnnn|nnnnnn-nnnnnn},{nnnnnn|nnnnnn},...}) - This statement specifies the sequence numbers of one or more trace entries that you want to print. 6 digits each.

CICS Trace Print Utility

- Parameters for the utility:
 - SHORT, ABBREV, or FULL
 - TRANID=(xxxx,yyyy) – one or more transaction codes
 - TERMID=(xxxx,yyyy) – one or more terminal identifiers
 - TASKID=(nnnnn,nnnnn) – one or more task numbers
 - KE_NUM=(xxxx,xxxx) – one or more KE entry hexadecimal values
 - ENTRY_NUM=(nnnnnn-nnnnnn) – specify a range of entry numbers
 - TIMERG=(hh:mm–hh:mm) – time range of trace entries
 - PAGESIZE=60 – specifies the number of lines on a page
 - UPPERCASE – specifies that output is to be upper case only
 - ALL (default) or EXCEPTION or TYPETR=(ddxxxx,ddxxxx-xxxx)
- Required is one of SHORT, ABBREV, and FULL (default)
- Selection options may refer to a single value, multiple values, or a range of values

Complete your session evaluations online at www.SHARE.org/Seattle-Eval

12

Trace print options (continued):

TIMERG=(hhmmss-hhmmss[,hhmmss-hhmmss,...]) - This statement specifies the time period or periods for which trace entries are to be printed.

PAGESIZE=(value) – Specifies the number of lines printed on a page, default is 55.

UPPERCASE – Specifies that you want the trace output in uppercase only.

ALL - Specifies that all trace entries in the auxiliary trace data set are to be printed, default value.

EXCEPTION – Specifies that only exception trace entries in the auxiliary trace data set are to be printed.

TYPETR={({ddxxxx|ddxxxx-xxxx}[,{ddxxxx|ddxxxx-xxxx}]) - This statement specifies the trace entry identifiers for the particular domain entries, specified by the domain or component id and a point id (hexadecimal value) within the domain.

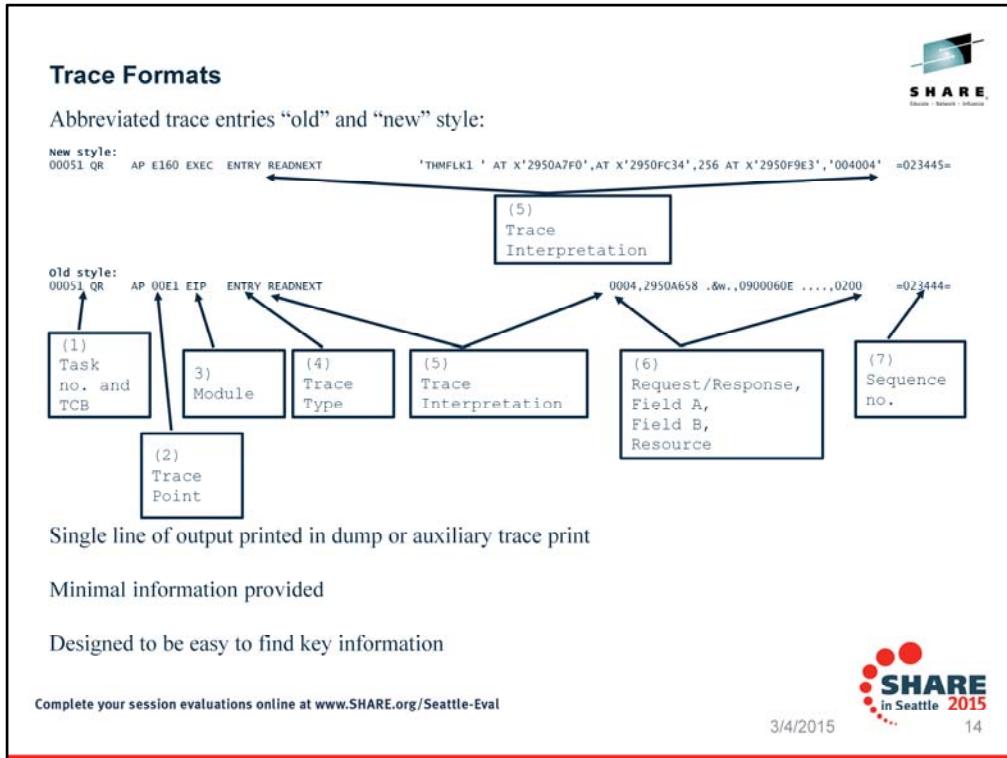

- Overview of Trace Formats

Complete your session evaluations online at www.SHARE.org/Seattle-Eval

3/4/2015

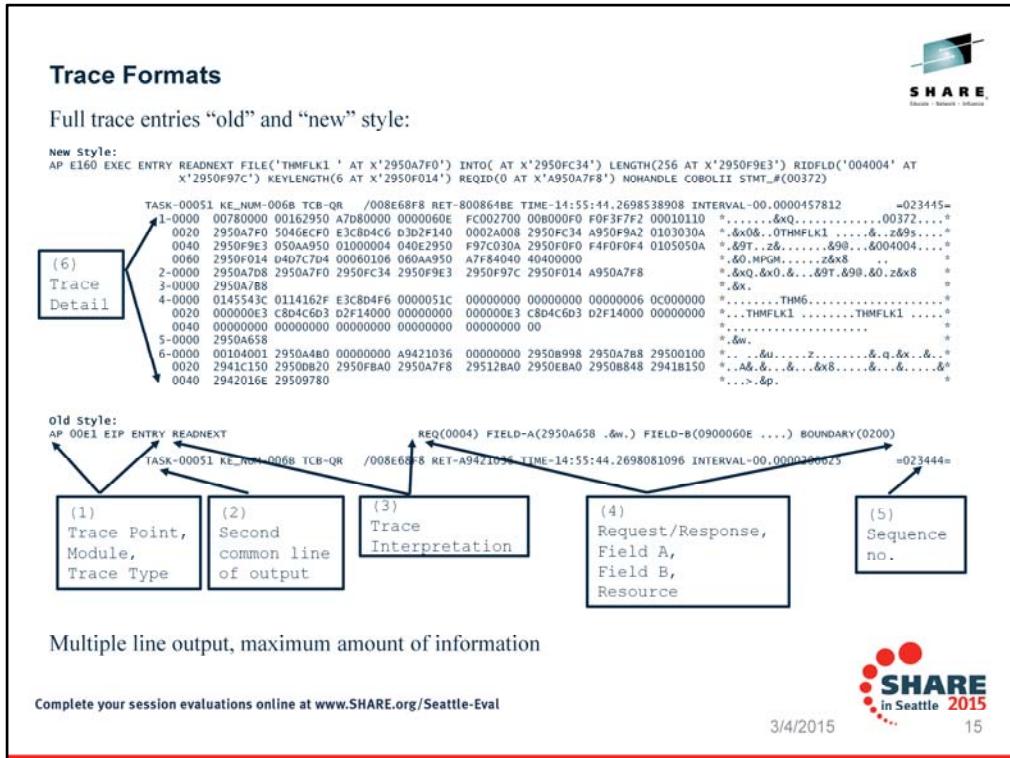

13

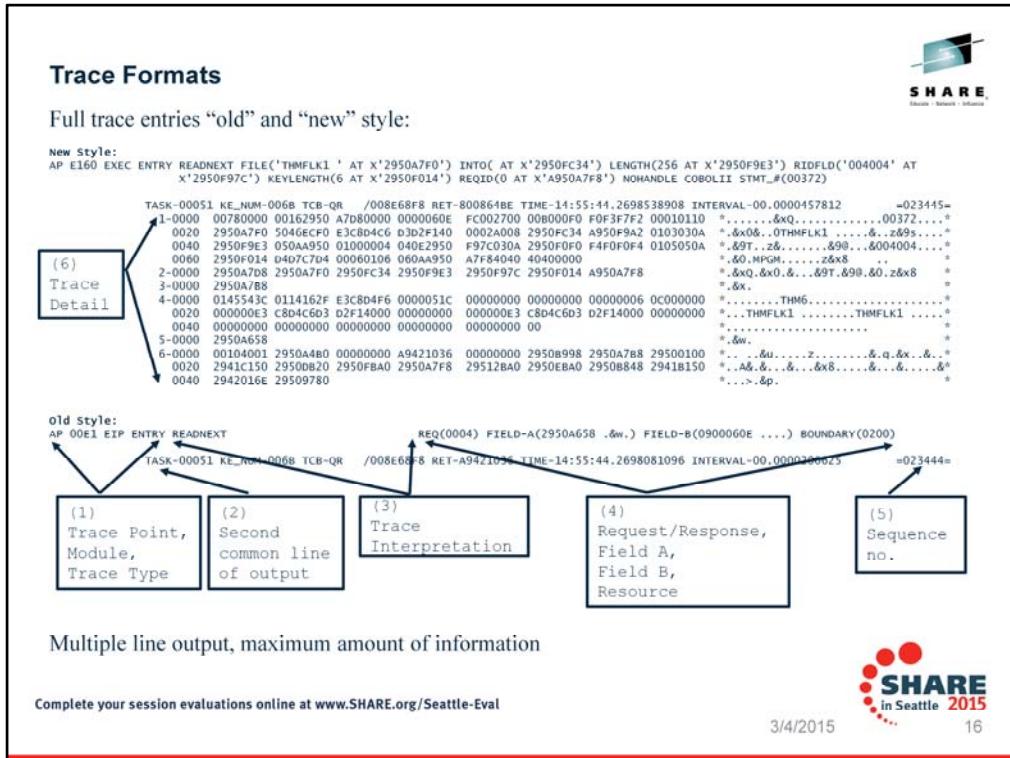

The abbreviated trace entries are a single line of output, providing the minimal amount of information. These type of entries will show in transaction dump output, system dump (IPCS) output on request, and the auxiliary trace print utility (DFHTU690) on request.

- (1) **Task identification number** or special id for certain AP domain system transactions (e.g., **TCP**). Also included in the first trace area is the TCB the task is dispatched on.
- (2) Indicates the originating place, *trace point*, where the event occurred. These do have some documentation provided in the CICS TS Trace Entries manual.
- (3) Identifies the **module in the AP domain or gate call being performed** where the event (code) being traced is located.
- (4) May be **ENTRY, EXIT, EVENT** or **DATA** specifying whether a call is being traced or a significant happening transpired or data exists which might be of interest. For each ENTRY there will be a corresponding EXIT trace entry. These can be used to establish exactly which module the task is in at that point in time.
- (5) Short "**English-like**" **explanation** of the contents of the trace entry consisting of request & options and other parameters
- (6) Coded *request, request dependent data fields* and *resource* without interpretation as found in Full Trace. Some requests name a particular associated resource, *not present on most entries*.
- (7) An identifying number in order to **relate abbreviated and full trace** entries to one another.

The full trace entries are a single line of output, providing the minimal amount of information. These type of entries will show in transaction dump output, system dump (IPCS) output on request, and the auxiliary trace print utility (DFHTU690) on request.

- (1) Indicates the trace point, module name or gate call, plus the trace entry type. The trace points do have some documentation provided in the CICS TS Trace Entries manual. The module names are relative to modules in the AP domain. The gate calls show the function of a domain is being invoked. The trace entry type May be **ENTRY**, **EXIT**, **EVENT**, **CALL**, **RETUR**, ***EXC*** or **DATA** specifying whether a call is being traced or a significant happening transpired or data exists which might be of interest. **For each command performed by an application program there will be an ENTRY & EXIT combination.** The EIP trace type entries can be used to provide a profile of the commands executed by the application.
- (2) The second line of the trace entry contains several key pieces of information. The first (TASK=) identifies the task number, component of the AP domain or CICS domain with which the entry is associated. This is followed by the KE domain task number assigned plus the TCB address. This information can provide a tie back to the KE summaries and Kernel Error data. Next id the return address (RET-) or Reg. 14, to the module which has issued the call. When the entries show a module of EIP then the return address can be tracked to the application call statement for the CICS command. Next is the time at which the trace entry was recorded with a very small fraction of a second in time. Last the INTERVAL is the amount of time between this trace entry and the previous entry. This can at times indicate a potential performance issue when the time interval is considered too large (asterisk (*) when over 50 ms).
- (3) Short "English-like" explanation of the contents of the trace entry request type, with pertinent qualifying information. However, the new style trace entries contain several keyword(value) pairs which provide a very detailed description of the attributes for an CICS command.

Full Trace Format (continued):

- (4) **REQ()** – Combination of bit settings which indicate what type of request/response is being recorded in which AP domain component.

FIELD-A() and **FIELD-B()** – Interpretation totally dependent upon the request type and trace point involved.

The User Handbook and Problem Determination Manual will contain a description of the information found in FIELD-A and FIELD-B. However for the **AP 00E1** entries which we are most concerned about, contain the following information:

For ENTRY – FIELD-A contains **address of the program RSA**; which is the DSA of PL/I or C, the TGT of COBOL and DFHEISTG of assembler. FIELD-B contains the execution key in the first byte, plus **EIBFN** or function code in the last two bytes.

For EXIT – FIELD-A contains the same value as found in **EIBRESP2**, and FIELD-B contains the **EIBRESP** value in the first two bytes, plus **EIBFN** in the last two bytes,

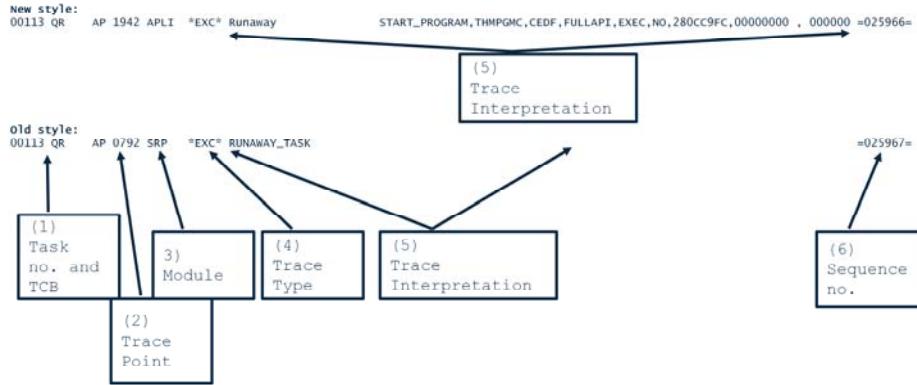

RESOURCE() – Some requests name a particular resource which the component is manipulating identified by the **RESOURCE()** keyword. Depending upon the trace point involved, this may represent a file name, TS or TD queue name, a terminal identifier, etc.

- (5) An identifying number in order to relate abbreviated and full trace entries to one another. *Not an actual part of the trace entry, but rather a number assigned during the printing of the trace entries.*
- (6) Each “New Style Full Trace” contains many data areas associated with the trace entry. These are somewhat documented as part of the trace point documentation found within the CICS TS Trace Entries manual.

Trace Formats

Abbreviated “exception” trace entries “old” and “new” style:

Single line of output printed in dump or auxiliary trace print

Minimal information provided

The full exception trace entries are a single line of output, providing the minimal amount of information. These type of entries will show in transaction dump output, system dump (IPCS) output, and the auxiliary trace print utility (DFHTU690) at all times.

- (1) Indicates the trace point, module name or gate call, plus the trace entry type. The trace points do have some documentation provided in the CICS TS Trace Entries manual. The module names are relative to modules in the AP domain. The gate calls show the function of a domain is being invoked. The trace entry type May be ***EXC*** or ***EXCU** specifying whether the exception is CICS or USER generated, respectively.
- (2) The second line of the trace entry contains several key pieces of information. The first (TASK=) identifies the task number, component of the AP domain or CICS domain with which the entry is associated. This is followed by the KE domain task number assigned plus the TCB address. This information can provide a tie back to the KE summaries and Kernel Error data. Next id the return address (RET-) or Reg. 14, to the module which has issued the call. When the entries show a module of EIP then the return address can be tracked to the application call statement for the CICS command. Next is the time at which the trace entry was recorded with a very small fraction of a second in time. Last the INTERVAL is the amount of time between this trace entry and the previous entry. This can at times indicate a potential performance issue when the time interval is considered too large (an asterisk (*) when over 50 ms).
- (3) Short **"English-like" explanation** of the contents of the trace entry request type, with pertinent qualifying information. However, the new style trace entries contain several keyword(value) pairs which provide a very detailed description of the attributes about why the exception occurs.
- (4) An identifying number in order to relate abbreviated and full trace entries to one another. *Not an actual part of the trace entry, but rather a number assigned during the printing of the trace entries.*
- (5) Each “New Style Full Trace” contains many data areas associated with the trace entry. These are somewhat documented as part of the trace point documentation found within the CICS TS Trace Entries manual.

The slide shows a comparison between the three different formats of the trace entries output from the trace print utility, DFHTU690. The same two trace entries are shown in the different formats to provide a good comparison. As you can see, the **abbreviated format** is a single line of output with only the minimal of information. The **short format** is 1, 2, or 3 lines of output from the utility. Included are some **keyword(value)** attributes, plus the inclusion of the **RET-** and **time fields**. The latter being something we have wanted for quite awhile on the abbreviated entries. Last are the **full formatted** entries, which contain not only the same information as the short entries but also several data areas. The data areas provided are somewhat documented and are deemed relevant to the entry produced.

If you will notice, these entries represent the fact that an application has issued a **READQ TS** command. These are produced at “entry” to the command level interface from the application program. All of the information represents the command which CICS is about to execute.

The **AP 00E1 EIP** entry is the result of EI trace level 1 and the **AP E160 EXEC** entry is the result of EI trace level 2. The AP 00E1 shows the minimal of information. However, the AP E160 entry includes the important information like the name of the TS queue, the **LENGTH** of the item and is number (**ITEM**), plus the COBOL statement number (**COBOL_STMT_#**).

The **AP 00E1** short and full entries both provide the address of the command within the program, **RET-** attribute. This can be useful in providing a profile of the commands being executed by the application, especially if you do not have the source code. This can also get you back to the logic in the source program to more easily resolve problems. Please do not use the attribute on the AP E160 entries as this relates to a CICS module within the AP domain normally. **RET-**

On the **AP E160** full trace entry, some key data areas are #4 – the EIB at this point in time, #5 – the address of the RSA (register save area), and #6 – actual RSA.

The slide shows a comparison between the three different formats of the trace entries output from the trace print utility, DFHTU690. The same two trace entries are shown in the different formats to provide a good comparison. As you can see, the **abbreviated format** is a single line of output with only the minimal of information. The **short format** is 1, 2, or 3 lines of output from the utility. Included are some keyword(value) attributes, plus the inclusion of the **RET-** and **time fields**. The latter being something we have wanted for quite awhile on the abbreviated entries. Last are the **full formatted** entries, which contain not only the same information as the short entries but also several data areas. The data areas provided are somewhat documented and are deemed relevant to the entry produced.

If you will notice, these entries represent the fact that an **READQ TS** command has been done. These are produced at “exit” from the command level interface returning to the application program. All of the information represents the command which CICS has just completed.

The **AP 00E1 EIP** entry is the result of EI trace level 1 and the **AP E161 EXEC** entry is the result of EI trace level 2. The AP 00E1 shows the minimal of information. However, the AP E161 entry includes the important information like the name of the TS queue, the **LENGTH** of the item and is number (**ITEM**), plus the COBOL statement number (**COBOL_STMT_#**). Since this entry is the result of a completed command, the **RESP()** and **RESP2()** attributes are included to provide the status of command completion.

The **AP 00E1** short and full entries both provide the address of the command within the program, **RET-** attribute. This can be useful in providing a profile of the commands being executed by the application, especially if you do not have the source code. This can also get you back to the logic in the source program to more easily resolve problems. Please do not use the **RET-** attribute on the AP E161 entries as this relates to a CICS module within the AP domain normally.

On the **AP E161** full trace entry, some key data areas are #4 – the EIB at this point in time, #5 – the address of the RSA (register save area), and #6 – actual RSA.

This slide represents one EXEC CICS command with all possible Level 1 and 2 entries turned on. The intent is to just show the amount of trace data with is possible with the default option settings. Also this illustrates the number of **User Exit (UEH module)** entries which may be produced. There are many IBM and vendor products which implement **XEIN**, **XEOUT**, **XRMIN**, and **XRMOUT** user exits. Can you imagine the number of entries produced by these user exits. This is why we have turned off these entries.

CICS Command Entry with UE Enabled

EXEC CICS command trace with inclusion of user exit trace entries:

```

This slide is a continuation of the EXEC CICS command with all possible trace entries. Again, notice the number of user exit trace entries which are produced by the common utilized user exit points. Also, please notice the last three trace entries, **AP E161**, **APE111**, and **AP00E1**. They correspond to the first three trace entries on the previous slide, **AP 00E1**, **AP E110**, and **AP E160**. These are produced by STNTREI=(1,2) and SPCTREI=(1,2) SIT overrides and provide the most information about the commands executed by the application programs.

Tokens in Trace Entries

Tokens:

Tokens which may be of use:

A **Token** is an identifier for an object. This enables reference to objects by different domains in a manner unique to each domain. **Tokens may be used to analyze task interaction from the trace evidence.** **Objects** that have tokens associated with them include:

- Domains** A unique number from 1 to 21, KE Table Entry for the domain. Not the same as Domain ID, but there is a one to one correspondence
- Locks** Returned by **ADD_LOCK** function of the **LMLM** gate in LM domain. Address of Lock Management Block used to lock a logical resource (**SHARED** or **EXCLUSIVE**)
- Storage** Returned by **ADD_SUBPOOL** function of the **SMAD** gate in SM domain. Address of Subpool Control Area (**SCA**) plus a unique number for **Subpools** each pool created.
- Programs** Returned by **DEFINE_PROGRAM** & (optionally) the **ACQUIRE_PROGRAM** function of the **LDLD** gate in LD domain. Address of Current Program Entry block (**CPE**) used to manage defined programs

There are many tokens associated with a task. Consider the token from the perspective of the owning domain and their part within task creation as follows:

Domain Involved/

Label In Trace

Description

Dispatcher (DS) For **CREATE_TASK: address of the DTA**. The value is returned on the **TCB_REPLY** and **TASK_REPLY** functions of the KEDS format gate in DS (in module **DSKE**). It is identified as **DS_TASK** in the Kernel Domain Summary.

TASK_TOKEN The value found on the **DSKE ENTRY** gate for function **TASK_REPLY** contains the address of a KE **TTE** (task table entry or "slot"). The value returned of the **DSAT EXIT** gate for function **ATTACH** contains the **block**, **cell** and **count** found on the DS Summary as the **DS_TOKEN** column.

TRANSACTION_TOKEN The value found on the **DSAT ENTRY** (Version 4.x only) gate for function **ATTACH** contains the address of the **TXN** (Transaction) in the first full word and the **packed task number** in the second.

26

There are literally hundreds if not thousands of exception trace entries possible within CICS. Most of which indicate a hard problem like an abend or critical resource shortage. However, many represent some lesser performance issue like thread or string wait conditions.

The application itself can generate exception trace entries, like the first one shown on this slide. Instead of the trace type being ***EXC***, it will be ***EXCU** to indicate an application generated entry. The trace data, resource information, and interpretation information are dependent on what the application program has supplied.

The second entry on this slide, trace type ***EXC***, represents a storage related problem. This entry is generated by CICS itself when an application program executes a FREEMAIN command and the storage area is damaged. Storage violations are only checked when the storage areas for a task are being freed. At the front and end of each acquired piece of storage is an eight byte field known as the **Check Zone**. These areas normally contain the storage subpool identifier, a literal character value. If either check zone does not contain this value then CICS considers the storage area to be violated. There is no way for CICS to know the extent of the storage overlay, just the fact that the first and last eight bytes are invalid.

Also, in looking at the "storage_check_failed.." entry, you will notice several associated data areas. These areas are somewhat documented in the CICS TS Trace Entries manual. While not all areas are thoroughly covered (the parameter list as an example), the key ones will have some meaningful description. In this entry, data areas 2, 3 and 4 are significant, respectively providing the address, first 64 bytes and last 16 bytes of the data area. As you can see, both the leading and trailing check zones do not contain the proper values.

This slide contains the exception trace entry produced by CICS for a storage violation when the storage is being freed at task end. This is normally when the majority of storage violations occur since most application programs do not issue FREEMAIN commands. As with the previous storage check failed trace entry, the data areas here may be useful. Data area 1 is the address of the storage area, while data area 2 is its length (in hex). Data areas 4 and 5 show up to 512 bytes at the start and end of the storage area, respectively. Also shown in data areas 6 and 7 area the areas before and after the violated area, up to 1024 bytes each. The latter two areas are presented in case the data may assist with finding the offending application program.

This slide contains the exception trace entry produced by CICS for a storage violation when the storage is being freed at task end. This is normally when the majority of storage violations occur since most application programs do not issue FREEMAIN commands. As with the previous storage check failed trace entry, the data areas here may be useful. Data area 1 is the address of the storage area, while data area 2 is its length (in hex). Data areas 4 and 5 show up to 512 bytes at the start and end of the storage area, respectively. Also shown in data areas 6 and 7 area the areas before and after the violated area, up to 1024 bytes each. The latter two areas are presented in case the data may assist with finding the offending application program.

- Application Profiling

- The next few slides represent our transaction THMY, which interacts with one of our DB2 regions.
- One of the goals here is to illustrate how you can tell just where your application program is in the scheme of things.
- Another goal is to provide insight into determining if the potential issue is part of CICS or some other resource manager.

Now to do a little application profiling with trace data. Our first example is a transaction which performs DB2 requests. While we will not go through the complete sequence of events, we will cover several key items in the CICS / DB2 interface. We will pay close attention to the bolded, underlined portions of these trace entries.

First let's call your attention to the first two trace entries, "**DS 0012 DSKE ENTRY TASK_REPLY**" and "**XM1305 XMTA ENTRY TASK_REPLY**". All transaction in CICS will start with these two trace entries. They represent the task passing any DS domain constraints like max. task, plus XM domain constraints like TRANCLASS. Although we will not show them, you will see the two corresponding "**EXIT TASK_REPLY**" trace entries as the last two trace entries for the transaction.

The next two high-lighted entries, **PG 0801** and **PG 0802**, represent the start of the transaction from a monitor, statistical point of view. At this point CICS will begin to capture resource utilization information for the task. Next you will notice that a **GETMAIN** is issued for **REMARK(AP_USER)** type of storage. This is where the AP domain begins to recognize the task and assign a task number, 56 in this case. You see another **GETMAIN** being done with a type of **REMARK(EI_TRACE)**. It should be noted that this is CICS performing the command since the initial application program is yet to be invoked. However, two key attributes on any **GETMAIN** trace entries will be the **GET_LENGTH()** and **ADDRESS()**. These attributes proved the length of the acquired storage and its address, respectively. When working with a storage violation dump, dump codes **SM0102** and **SM0103**, these can be used to help find out which transaction really owns the storage area being violated.

We have left out a few entries as indicated by the sequence numbers =001829= and =001835=. The trace point **RM 0209** provides us with the assigned, unique **UOW_ID()** or **Unit of Work Identifier**. This can be used to assist with resolution of indoubt or shunted UOWs. The UOW_ID is also used as a token to manage UOWs across related subsystems like DB2 or WebSphere MQ.

33

The next entry, “**PG 0901 PGPB ENTRY INITIAL_LINK**” indicates that CICS is about to pass control to the first application program associated with the transaction. Notice that the task ends up being suspended as indicated by the “**DSSR ENTRY SUSPEND**” trace entry. The **SUSPEND_TOKEN()** is used as a token for DS domain to keep track of the tasks being put into various wait states, plus to identify which task is being resumed when the wait condition is resolved. The main reason for the task wait state is because the program has to be loaded into memory. By subtracting the time on the DSSR ENTRY trace from the DSSR EXIT trace you can obtain the approximate time it took to complete the load request, **.0212 seconds** in this case. At times one of the mysteries of poor task performance may in fact be the loading of a large application program, i.e. something greater than 1 MB. Loading of large programs will require many I/Os to read in the program from the load library, plus the potential need to perform storage compression or acquire more extents of storage to hold the program.

Finally we have high-lighted the **ENTRY_POINT()** and **LOAD_POINT()** attributes on the “**LD 0002 EXIT**” trace entry. When working with application profiling, these can be quite useful to track back the commands shown in trace back to the actual source program. They can also be used to assist with problem resolution when working with exception trace entries which are the result of an abend.

34

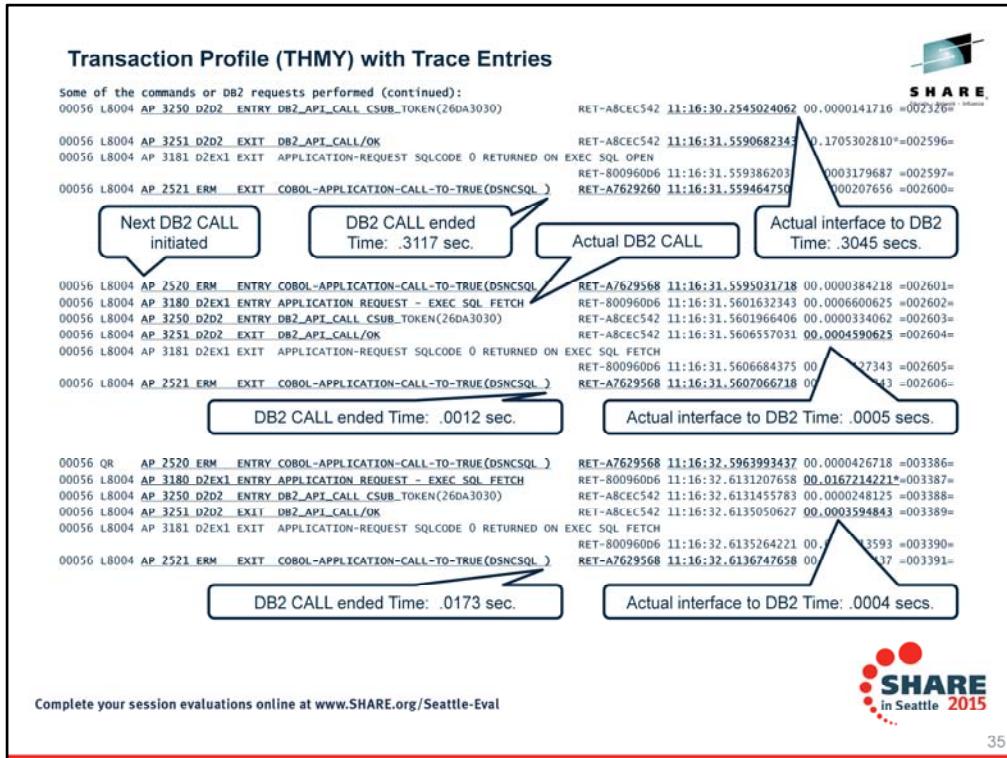

The first four high-lighted trace entries on this slide show two initial GETMAINS performed at the start of a task for LE related areas. While these could be important when using LE data areas to debug applications, our main purpose is to point out the **GET_LENGTH()** and **ADDRESS()** attributes. When working with a storage violation dump, it may be necessary to find the original GETMAIN request for a storage area to determine which task owns the storage.

The third GETMAIN request is for the copy of the “dynamic storage area” (COBOL working storage) for the initial program. This storage area is described in the compile listing for the application program involved and can be useful when you need to determine values for attributes used within the program. However, that is the subject for another presentation or our CICS Problem Resolution course (sorry for the little plug).

The first actual command our application issues is a **GET CONTAINER** command. Here you see the EIP ENTRY and the EIP EXIT trace entries. By subtracting the time on the ENTRY from the time on the EXIT you can tell the amount of time it takes to process the command. While this may seem to be minimal, so was the data area involved. All containers are kept “above the bar” until retrieved and then **moved to below the bar** for use. Since containers can be very large (100s of megabytes), this move operation can be quite significant.

The next high-lighted entry, **ERM ENTRY**, represents the start of a DB2 call. Besides noting the **RET-** attribute, make a mental note of the **TIME** value. We will use the time value soon.

The last high-highlighted entry, **D2EX1 ENTRY**, represents the actual DB2 call being performed, an **SQL OPEN** request in this case. This may be considered to be start of the DB2 request, but we are still within the resource manager code in the CICS region.

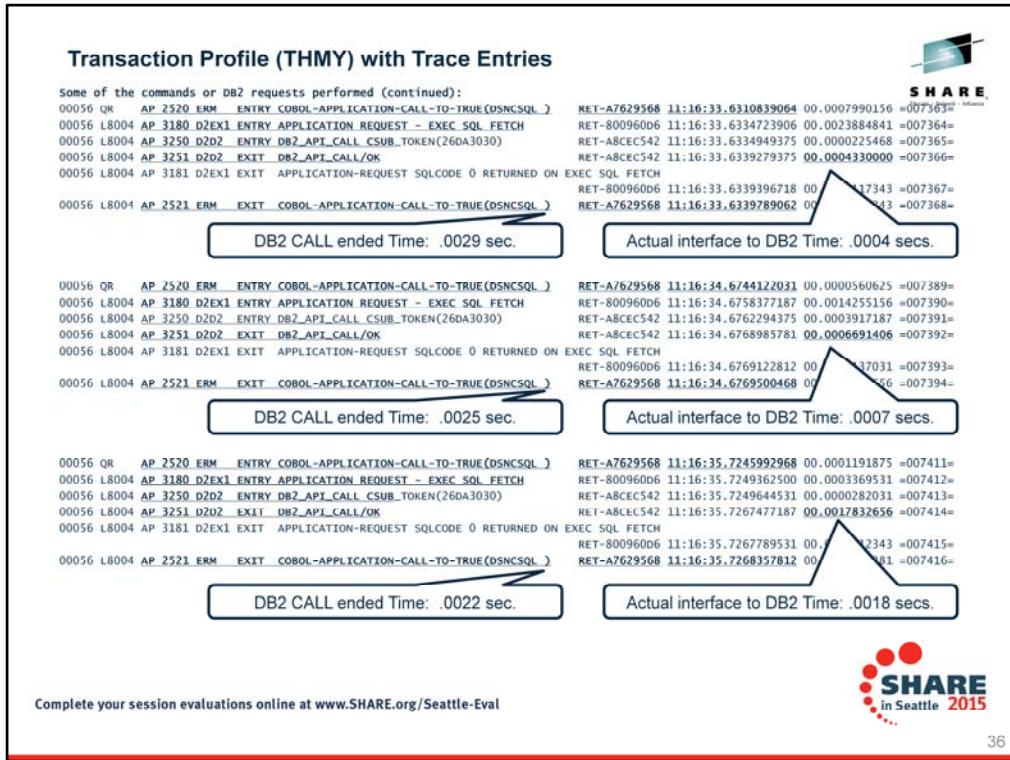

35

The first entry, **D2D2 ENTRY**, on this slide is truly the start of the DB2 request. It is produced just prior to transfer to the DB2 region itself. The next entry, **D2D2 EXIT**, is produced upon return from the DB2 region. By subtracting the ENTRY time from the EXIT time you can determine how long the request took to process in the DB2 region. In our example, over .3 seconds. This is a reasonable example of how the coding of the SQL request can have a profound affect on response times. Our SQL OPEN has an ORDER BY clause which forces a sort of approximately 50,000 rows.

Next you see the **ERM EXIT** trace entry. This signifies the actual return back to the application program. One could also consider this to be the total DB2 response time since the resource manager is in fact part of the DB2 interface. We will leave this up to you to determine. As you can see, the actual difference in time is minimal.

You then see the next DB2 call being performed, an **SQL FETCH** call. Again, the actual DB2 time is only .0005 seconds, D2D2 ENTRY to D2D2 EXIT trace entries. However if you consider using the ERM ENTRY to ERM EXIT trace entries the time is over double.

On the same slide we have included a third DB2 request to simply show the fact that there may be small variances in each DB2 request.

36

For the final slide of our THMY transaction we have included three more DB2 calls. This is just to provide you with more examples of the variance in DB2 requests which can occur even when performing the same SQL command, FETCH commands in our example.

- The next few slides represent our transaction THM4, which provides a look at profiling of a normal CICS application program.
- The goal is to not cover all possible situations, but rather to provide you with a method to accomplish this at your sites.

This slide shows another transaction, THM4, which we will use as an example of transaction profiling. We have chosen to begin well into execution of our application program since our goal is to provide a useable technique and not to completely profile our application in this short session.

So the key is to capture key information from either the **EIP ENTRY** or **EIP EXIT** trace entries, not both. In our example we will use the EIP ENTRY trace entries to gather the necessary information. For each EIP ENTRY we will record the trace sequence number, command being executed, key resource being worked upon, and the RET- address back to our program.

For the first command, trace entries **031515** and **031516**, we see an **ENQ** command. The resource is a character string which we obtain the enqueue upon. Plus the return address on trace entry 031515 is **27527036**.

The next command, trace entries **031523** and **031524**, is a **READQ TS** command. The queue name involved is **THEMISTX** and the return address is **27527152** on trace entry 031523.

The last command on this slide, trace entries **031529** and **031530**, is a **DEQ** command. The resource is the same character string from the previous ENQ command and the return address is **27527246** on trace entry 031529.

Transaction Profile (THM4) with Trace Entries

Trace Entries for Application profiling (continued):

The first command on this slide, trace entries **031537** and **031538**, is a **ASKTIME-ABSTIME** command. While we cannot see all of the attribute specified, we can see the return address of **27526DA0** on trace entry **031537**.

The next command, trace entries **031541** and **031542**, is a **FORMATTIME** command. This command also does not have any description of its attributes. However, we do have the return address of **27526F42** on trace entry **031541**.

The last command, trace entry **031545**, is a **ENQ** command. The return address on this entry is **27527036**.

The first command, trace entry **031546**, is a **ENQ** command and actually the same one as entry 031545 on the previous slide.

The next command, trace entries **031553** and **031554**, is a **READQ TS** command. The queue name is **THEMISTX** and the return address is **27527152**.

The next command, trace entries **031559** and **031560**, is a **DEQ** command. The resource is the character string found on the previous ENQ command and the return address is **27527246** on trace entry 031559.

The first command, trace entries **031567** and **031568**, is a **ASKTIME-ABSTIME** command. There are no significant attributes shown but the return address is **27526DA0** on trace entry 031567.

The next command, trace entries **031571** and **031572**, is a **FORMATTIME** command. There are no significant attributes on this command either, with a return address of **27526F42** on entry 031571.

The last command, trace entries **031575** and **031576**, is a **ENQ** command. The resource is a character string and the return address is **27527036** on trace entry 031575.

```

We have stopped here in gathering the trace entries since the last one shown indicates that the application has suffered an abend.

It appears that the application has exceeded the amount of allowed processor time without yielding control to CICS.

Complete your session evaluations online at www.SHARE.org/Seattle-Eval

42

The first command, trace entries **031583** and **031584**, is a **READQ TS** command. The queue name is **THEMISTX** and the return address is **27527152** on entry 031583.

Now we see an exception trace entry (***EXC***) at entry number **031585**. This is for a “runaway task” or consumption of too much processor time without yielding control back to CICS. It should be noted at this point that it is possible to suffer an AICA abend even while processing EXEC CICS commands. So long as the commands do not require any form of a wait, the issuing application will gain control immediately and continue with its processing.

The commands **ASKTIME**, **FORMATTIME**, **ENQ** (successful), and **DEQ** do not relinquish control. Only the **ENQ** would cause a wait condition if it fails. The **READQ TS** command does not require a wait if the data items to be processed are already in buffers in memory.

Another command which might not relinquish control is a file control function which the records already reside in buffers in memory. So just because your application is executing commands, does not mean that it will relinquish control so that other applications can run.

Transaction Profile (THM4) with Trace Entries

Trace Entries for Application profiling (continued):

While we were traversing the trace entries we recorded key information about the EXEC CICS commands being issued.

This table reflects our findings, a program loop issuing CICS commands which do not relinquish control to CICS.

	Seq. Number	Command	Resource	RET Address ##
Recorded information AP 00E1 EIP and EXEC Trace points ## Remember, The x'80' bit On the address Indicates 31-bit mode	031515 / 031516	ENQ RESOURCE	Character string	27527036

So if you were jotting down the information as we went along, you would end up with a chart like the one on this slide. Stepping back a little to analyze these commands you will notice the loop of ASKTIME, FORMATTIME, ENQ, READQ TS, and DEQ commands. This is evident by the repeat in return addresses involved. Also the same queue name on the READQ TS command and the same character string on the ENQ or DEQ commands. In fact our application programs was in this loop of commands for over 1 1,000 times before failing with the AICA abend.

- The next few slides represent our transaction THM1, which provides a look at the process of task termination.
- While you will see a problem situation as part of this review, we will also expose the sequence of events which occur at time point in the life of a CICS task

On this next set of slides we are going to take a look at what happens during task termination. So we begin with trace entry =00699=, which is the **RETURN** command. This is one of the few “ENTRY” trace points for which there is not a corresponding “EXIT” trace point. Again, the **RET-** attribute will reflect the statement in the application program where the command is done.

The only other high-lighted trace entry on this slide is the last line, entry number =000719=, which is a PG domain “ENTRY”. This is the point at which any CHANNEL and CONTAINERS will be deleted on an EXEC CICS RETURN command without the CHANNEL() attribute.

This slide begins with the continuation of the CONTAINER cleanup, trace entry numbers =000720=, =000721=, =000724=, and =000727=. We have purposely turned on the PG domain trace entries just to show where the cleanup of the CONTAINERS is performed. Normally we recommend to not include PG domain tracing in the normal scheme of events.

The next high-lighted “ENTRY”, number =000733=, represents the start of the process to commit any file or data base updates as part of task termination. Associated with this entry are several “EVENT” trace entries which reflect the coordination with various other CICS components. Here you see the interaction with file control (FC), Enqueue domain (NQ), AP domain (APUS), and we are not sure what (LT) represents.

The first high-lighted trace entry, number =000746=, represents the writing of the log data as part of the commit process. As you can see, the log records are being written to DFHLOG as indicated by the **RESOURCE_NAME(DFHLOG)** attribute. This is to ensure that these updates are made permanent and will not be rolled back if CICS were to crash and be “emergency restarted”.

The next high-highlighted trace entry, number =000754=, indicates the coordination with the Resource Manager Interface (**RMI**). This would include coordination with **DB2** or **MQ** if necessary.

Finally we see the last high-highlighted trace entry, number =000758=, which is the “EXIT” that corresponds to the ENTRY we saw a couple of slides previous. As you can tell, the commit of the protected resources has completed successfully. This is clearly indicated by the **RESPONSE(OK)** attribute.

Trace entry numbers =000767= and =000769=, represent the freeing of any terminal data areas associated with the task. This would include the last SEND MAP or SEND command output, which should now be displayed on the user's terminal. As we mentioned earlier in this session, it is at this time when CICS checks for storage violations. If the terminal data area were corrupted, we would see the *EXEC* trace entry here.

The next high-lighted trace entry, number =000778=, indicates the point at which the last remnants of the task have been removed from the AP domain. We no longer have an application transaction as far as CICS is concerned.

The last high-lighted trace entry, number =000782=, indicates the start of the process to cleanup all storage acquired by the task during its execution. Again, it is at this point where CICS will check for storage violations. Most applications do not cleanup the storage themselves but rather let CICS perform this function at this point in time.

Transaction Profile (THM1) with Trace Entries

```

During the last several slide we have covered the process of task termination for one of our small test applications.

This is where storage violations are normally detected, after most of the tracks of the task are gone from the CICS region.

This is why trace can be a valuable tool to help you resolve storage violations, especially in larger application environments.

Complete your session evaluations online at www.SHARE.org/Seattle-Eval

49

As you can see by trace entry number =000787=, CICS has detected a bas storage area. This is clearly indicated by the *EXC* trace entry. Think about what we have just gone through on the past few slides, task termination events as part of the application issues EXEC CICS RETURN command. We have committed file, data base or even MQ messages during this process. Now CICS has encountered a violated storage area and the task is essentially done, no task to abend an roll back at this point.

This is one reason why resolving a storage violation is one of the hardest problems to resolve since the application tracks have already been removed. We are performing this test in a controlled region. Can you imagine this happening in one of your production regions with hundreds if not thousands of task per second going on. We could see the interleaving of a large quantity of trace entries for many different tasks at this point in time.

The last high-lighted trace entry, number =000788=, indicates that CICS is about to issue the “DFHSM0102” message to indicate the storage violation and take the SVC dump for you to resolve the problem.

- The next few slides represent our transactions THMD and THME, which provides a look potential problems due to concurrent task execution.
- This is not meant to be an in depth look at potential problems, but ones which might occur due to operating in a common storage (same address space) environment.

51

Trace entry numbers =000413= and =000414= show the START command being issued for transaction **THMD**. Many applications are started asynchronously in CICS, included MQ triggered transactions. Shortly after this event we see trace entry number =000440=, which is CICS actually beginning to execute the transaction. We then see trace entry number =000454=, which is the completion of the START command. All of this being performed by our transaction **THMF** (task #122).

We now see transaction THMD (task #123) coming to life. The first two trace entries for each CICS application task will be the **DSKE** and **XMTA ENTRY TASK_REPLY**, as seen in entry numbers =000458= and =000459= respectively.

Trace entry numbers =000509= and =000510= represent the loading or acquiring of the initial program involved in the transaction. In other trace entries we have omitted you would see the program name, **THMPGMA** in this case. The importance of these entries is to obtain the **ENTRY_POINT()** and **LOAD_POINT()** attributes to allow you to obtain offsets for commands back to the source code.

Finally we see trace entry numbers =000588= and =000591=, which represent the first command our program executed. The command was an **ASSIGN TWALENG() SYSID() STARTCODE()** in this program.

Transaction Profile (THMD and THME) with Trace Entries

A look at asynchronous tasks plus a couple of abends (continued):

Transaction THMD continues execution with the command ADDRESS TWA() as seen in trace entry numbers =000592= and =000595=.

The next command is LINK PROGRAM() CHANNEL() as seen in entry numbers =000596= and =000597=. The program being invoked is **THMPGMB**, with channel **THEMISCHNL**.

As with any program invocation, we will be able to obtain the **ENTRY_POINT()** and **LOAD_POINT()** in an LD domain trace entry as seen in number =000600=.

We have omitted many trace entries for program THMPGMB initializing to show the first command it issued. The GET CONTAINER command seen in entry numbers =000623=, =000624=, and =000632=.

Next the program issues an XCTL PROGRAM() CHANNEL() command to pass control to THMPGMC as seen in trace entry numbers =000633= and =000634=.

Finally on this slide is the LD domain trace entry number =000637= where we can obtain the **ENTRY_POINT()** and **LOAD_POINT()** for **THMPGMC**.

The first command executed by THMPGMC is an ASSIGN CWALENG() as seen in trace entry numbers =000685= and =000688=. This is followed by the ADDRESS CWA() command as seen in entry numbers =000698= and =000692=.

The next command performed is a GET CONTAINER for container THEMISCONT as seen in entry numbers =000693=, =000694=, and =000702=.

The execution of a GETMAIN command for 512 bytes of storage is next, entry numbers =000703=, =000704=, =000707=, =000709=, and =000710=. The address of the acquired storage (27A1C3A8) can be found in both entry numbers =000707= and =000709=. At times it may be necessary to determine the actual owner of storage when working with a difficult storage violation problem.

A second GETMAIN command for 512 bytes of CICSDATAKEY storage is performed as seen in entry numbers =000711= and =000712=.

On the top of this slide we see the end of the GETMAIN command from the previous slide in entry numbers =000715=, =000717=, and =000718=. Again the acquired storage address (**2943A008**) can be seen in entry numbers =000715= and =000717=. After this, THMD relinquished control due to a command which caused a wait condition.

We then see THMF (task #122) gain control once again and execute another START command for transaction THME. All of the trace entries in this small section are from that START command. The task also performs a function which causes THMF to relinquish control back to CICS.

Next we see the beginning of task #124, transaction THME as indicated by entry numbers =000780= and =000781=. We have omitted many trace entries from the initiation of the task to show the LD domain entries, numbers =000829= and =000830=, for program **THMPGMA** which is the initial program for the transaction..

On this slide we see transaction THME executing its first command, an ASSIGN TWALENG() SYSID() STARTCODE(). This can be seen in entry numbers =000908= and =000911=.

Transaction THME continues execution with the command ADDRESS TWA() as seen in trace entry numbers =000912= and =000915=.

The next command is LINK PROGRAM() CHANNEL() as seen in entry numbers =000916= and =000917=. The program being invoked is **THMPGMB**, with channel **THEMISCHNL**.

As part of the LINK command we see the LD domain entry numbers =000919= and =000920=, which will provide us with the **ENTRY_POINT()** and **LOAD_POINT()**.

We have omitted many trace entries for program THMPGMB initializing to show the first command it issued. The GET CONTAINER command seen in entry numbers =000943=, =000944=, and =000952=.

Next the program issues an XCTL PROGRAM() CHANNEL() command to pass control to THMPGMC as seen in trace entry numbers =000953= and =000954=.

Transaction Profile (THMD and THME) with Trace Entries

A look at asynchronous tasks plus a couple of abends (continued):

As part of the XCTL command we see the LD domain entry numbers =000956= and =000957=, which will provide us with the **ENTRY_POINT()** and **LOAD_POINT()**.

We have omitted many trace entries for program THMPGMC initializing to show the first command it issued, an ASSIGN CWALENG command. This is indicated by entry numbers =001005= and =001008=. This is followed by an ADDRESS CWA() command as seen in entry numbers =001009= and =001012=.

We then see a GET CONTAINER command being issued as seen in entry numbers =001013=, =001014=, and =001022=. This is for container **THEMISCONT**, which has a length of **32 bytes**.

Immediately after the GET CONTAINER command we see that transaction THME (task #124) causes a **"Program-check"** as indicated by entry numbers =001023= and =001024=. Since this example is showing short format trace entries we do not see a lot of information about the abend. We will next have a look at their full trace counterparts where a bit more information is provided.

The next trace entry on this slide, number =001029=, provides us with the message number (**DFHSR0622**) and dump code (**SR0622**) being issued by CICS. This is followed by another ***EXC*** exception trace entry, number =001040=. We will also look at its full trace entry counterpart to see what more information is provided.

Transaction Profile (THMD and THME) with Trace Entries

A look at asynchronous tasks plus a couple of abends (continued):

The first entry, number =001023=, is the full trace entry corresponding to the short trace entry of the same number on the previous slide. Here we see a couple of data areas with data area 1- being the parameter list, which is not fully documented. Data area 2- is the Kernel Error Data table entry for the task, which is document in the CICS Data Areas manual. We will describe it a little bit with the next full trace entry.

The second full trace entry, number =001040=, corresponds to the short entry of the same number on the previous slide. This entry is documented in the CICS Trace Entries manual. First have a quick look at the attributes provided, **PROGRAM(THMPGMC)**, **OFFSET(00001F3C)**, and **0C4_ON(EUDSA)**. From these we gain knowledge of the offending program, plus the offset to the instruction within the program. We can also see that the problem is in accessing a storage area in the EUDSA which we do not have addressability to, as indicated by the **0C4_ON(EUDSA)** attribute.

Data area 1- is labeled as **TCASRDAT** for trace point AP 0781 in the CICS Trace Entries manual. This provides us with the program name, KE error code, program offset, and some flags. These are what we see as the interpreted attributes mentioned above. Data area 2- is labeled as **TCAPCSTG** or the storage hit indicator. Data area 3- is the Kernel Error Data table entry. This is fully documented in the CICS Data Areas manual. However a few key offsets are:

- +0 – which is the System and User abend codes
- +40 – which is the PSW at the time of the abend
- +68 – which is the saved registers (8 bytes each) at the time of the abend

While not clearly indicated, with a little research you would be able to determine that THME (task #124) attempted to modify storage of another task. Both transactions are defined with ISOLATE(YES) and TRANISO(YES) has been specified.

Transaction Profile (THMD and THME) with Trace Entries

A look at asynchronous tasks plus a couple of abends (continued):

58

We once again see transaction THMD (task #123) regain control. Almost immediately it too “**Program-checks**” as indicated by entry number =001111=.

We then see CICS begin the process of issuing the “**DFHSR0622**” message and prepare to take an SVC dump with code **SR0622** as indicated by entry number =001116=.

Next is the trace point AP 0781 exception entry, which will have some key information in its full trace entry that we can use to potential resolve the error. However, entry number =001127= is the short trace entry which does not contain this expanded information.

We the see the corresponding full trace entry to short entry number =001111=. As mentioned on an earlier slide, data area 1- is the parameter list and not fully documented. Data area 2- is the Kernel Error Data table entry, which we will again cover on the full trace counterpart to entry number =001127=.

Transaction Profile (THMD and THME) with Trace Entries

A look at asynchronous tasks plus a couple of abends (continued):

This slide contains the full trace entry counterpart to short entry number =001127=. Once again this entry is documented in the CICS Trace Entries manual. First have a quick look at the attributes provided, **PROGRAM(THMPGMC), OFFSET(00001E7C), and OC4_ON(ECDSA)**. From these we gain knowledge of the offending program, plus the offset to the instruction within the program. We can also see that the problem is in accessing a storage area in the ECDSA (CICS mode storage) which we do not have access to, as indicated by the OC4_ON(ECDSA) attribute.

Data area 1- is labeled as **TCASRDAT** for trace point AP 0781 in the CICS Trace Entries manual. This provides us with the program name, KE error code, program offset, and some flags. These are what we see as the interpreted attributes mentioned above. Data area 2- is labeled as TCAPCSTG or the storage hit indicator. Data area 3- is the Kernel Error Data table entry. This is fully documented in the CICS Data Areas manual. However a few key offsets are:

- +0 – which is the System and User abend codes
- +40 – which is the PSW at the time of the abend
- +68 – which is the saved registers (8 bytes each) at the time of the abend

Since THMD transaction and its programs are defined with TASKDATAKEY(USER) and EXECKEY(USER) respectively we are not permitted to modify CICS mode storage. This is also an indication that we have specified SI override parameter **STGPROT(YES)**.

On the last slide of this series we have included the trace entries which show the end of both THMD and THME transactions. This to show that even if tasks do abend they must go through back-out processing as indicated by entry numbers =002718= and =004174=.

You will also notice that the storage for each associated task must be cleaned up as indicated by entry numbers b and =004179=. Even though the tasks have abended, another abend could occur at this point if one of the storage areas was involved in a storage violation.

Finally you will notice the corresponding "EXIT" trace entries to the "ENTRY" trace entries we covered at the start of both tasks. Trace entries =002741= and =002742= for task #124 (THME), plus entries =004199= and =004200= for task #123 (THMD) will indicate the true end for each task.

While both of these problems are uncovered due to SI parameter options we have chosen, please notice that CICS does not indicate them via any special message. Both simply appear as "Protection Exceptions" or 0C4s. The real indication of the special CICS handling is indicated by the DFHSR0622 message and the dump with a code of SR0622. You should never suppress the SR0622 SVD dump since it may be the only way to resolve the problem.

- The next few slides represent our transactions THMH and THMI, which provides a look potential file control problems due to concurrent task execution.
- This is not meant to be an in depth look at potential problems, but ones which might occur due to operating in the same region.

Now to have a look at a pair of transactions conflicting with each other as they access files. The first one, transaction **THMH task #91**, is the first to start up. This can be seen from entry numbers =000685= and =000686=. Transaction **THMI**, task #92, then starts up a short time later as seen in entry numbers =000739= and =000740=.

We then see the load of the initial program, **THMPGMB**, occurring in entry numbers =00857=, =000858=, and =000861=. These entries not only provide us with the program name but also its **ENTRY_POINT()** and **LOAD_POINT()**.

Fast forward a little to the first command issued in task #91, which is the GET CONTAINER as seen in entry numbers =000947=, =000948=, and =000956=. This is for container **THEMISCONT** on channel **THEMISCHNL**.

The next command issued is a READ FILE() as seen in entry number =000957=. A bit more information will be found in the EI level 2 trace entry for this request.

63

In entry number =000958= we see the level 2 EI information. The **READ FILE() UPDATE** request is for file **THMFLK1** which will read a **256 byte** record “**INTO**” a **working storage area**. The request results in an I/O being necessary as evidenced by entry number =000964=, which is a DS domain **WAIT_MVS** with a **RESOURCE_TYPE(FCIOWAIT)**.

We then see task #92 regain control to acquire access to program **THMPGMB**. No actual load is required since task #91 paid the price to load the program into memory.

Since this task is using the same program, we see the GET CONTAINER command being performed in entry numbers =001049=, =001050=, and =001058=. While the container and channel names, **THEMISCONT** and **THEMISCHNL** respectively, appear to be the same you should know that each task will have its own unique channel and set of containers.

Next we see the **READ FILE() UPDATE** request for file **THMFLK2** being performed as seen in entry numbers =001059= and =001060=. This request is also for a **256 byte** record to be read “**INTO**” a **working storage area**. Once again the request results in an I/O being issued as seen in entry number =001066=, which is a DS domain **WAIT_MVS** with a **RESOURCE_TYPE(FCIOWAIT)**.

Next we see task #91 regain control after its I/O request completes and CICS performs an ENQ command, entry number =001068= for a key of **111111**. CICS will always do this enqueue for the key of the record plus the address of the base cluster control block or **BCCB**. This is the way CICS protects two tasks from updating the same record.

Task #91 was able to acquire the ENQ lock as evidenced by trace entry number =001071=.

We then see the READ UPDATE command complete as seen in entry numbers =001081= and =001082=. In fact the **INTO()** attribute contains the data record or at least some of it. Also the command completed successfully as indicated by the **RESP()** and **RESP2()** attributes. After this command, task #91 performs a function which causes it relinquish control back to CICS.

We then see task #92 regain control after its I/O completes. Again this is evidenced by the successful ENQ command issued by CICS in entry numbers =001191= and =001192=. The enqueue is for the BCCB of THMFLK2 with a key of 999999.

With the lock on the record we then see the completion of the READ UPDATE request in entry numbers =001206= and =001207=. Once again you can see a portion of the record in the **INTO()** attribute. The command does complete NORMAL, as indicated by the **RESP()** and **RESP2()** attributes. This task then performs a function which relinquishes control back to CICS.

Task #91 regains control and performs a second **READ FILE() UPDATE** as seen in entry numbers =001578= and =001579=. This is for file **THMFLK2** to read a 256 byte record into a working storage area.

The second **READ FILE()** cannot proceed since the ENQ request for the key of 999999 against the BCCB of file **THMFLK2** fails with a exception **REASON(ENQUEUE_BUSY)**. Task #92 has already read the same record and obtained the lock on it. This can be seen in entry numbers =001593= and =001594=. The task now enters a wait state as seen in entry number =001596=. The **RESOURCE_TYPE()** and **RESOURCE_NAME()** indicate the actual wait condition.

65

Task #92 now regains control and performs its second READ FILE() UPDATE for file THMFLK1 as seen in entry numbers =002318= and =002319=. This request ends in a wait state as seen in entry number =002329=. The DS domain places the task into a wait with a RESOURCE_TYPE(FCPSSUSP) and RESOURCE_NAME(THMFLK1). This indicates a wait for a private string.

Next we see task #91 regain control as evidenced by entry numbers =002931=, =002932=, and =002933=. However, this is not a good event since we see an exception REASON(TIMED_OUT).

Entry number =002943= indicates that the ENQ request has failed to obtain the lock as task #92 still controls the record. This is a direct result of the fact that the transaction was defined with the SPURGE(YES) attribute with a reasonable value for DTIMOUT(). Without these attributes the task would have stayed in the wait state indefinitely and potentially cause CICS to “stall” as more and more tasks get backed up.

We then see the task get purged and the transaction dump of AFCY is produced, as evidenced by entry numbers =002935= and =005437=. The many trace entries eliminated between these two were CICS producing the transaction dump.

Task #92 now regains control since a string has been released with the purging of task #91. This can be seen in entry numbers =006010= and =006011=. However, task #91 has not completed its cleanup so this task cannot obtain the ENQ lock for the BCCB of THMFLK1 with a key of 111111 as seen in entry numbers =006012=, =006013=, and =006014=. Since task #91 still holds the ENQ this task receives the REASON(ENQUEUE_BUSY) status.

Task #92 now enters a wait state as seen in entry number =006015=. DS domain indicates the wait condition with a **RESOURCE_TYPE(ENQUEUE)** and a **RESOURCE_NAME(FCDSCRECD)**.

Finally task #91 completes its cleanup of resources as a result of being purged as seen by entry numbers =006205=, =006210=, =006224=, and =006225=. These represent the events which occur at task end.

Task #92 regains control with the obtaining of the ENQ lock as seen in entry number =006227=.

We then see the completion of the READ FILE() request for file THMFLK1 as seen in entry numbers =006239= and =006240=. We can see the first portion of the record in the **INTO()** attribute, plus the indication of **NORMAL** completion by the **RESP()** and **RESP2()** attributes.

Task #92 then proceeds with the rest of its function and ends normally as seen in entry numbers =006318=, =006323=, =006336=, and =006337=.

- The next few slides represent our transaction MF00, which invokes a web service to acquire some data from a provider application.
- This is not meant to be an in-depth look at all CICS web service process, just a quick overview.

68

Task #136 is the “requester” application in our case. So we simply show the PUT CONTAINER being executed first, entry numbers =000615=, =000616=, and =000626=. You will notice that the CONTAINER name is DFHWS-DATA. This is the default container name used to hold your data, both request and response, unless you specify the CONTID option in DFHLS2WS or DFHWS2LS jobs.

Next we see the INVOKE SERVICE command being performed, entry numbers =000627= and =000628=. The SERVICE name, THMF00Req, is the name for this CICS requester application. We used a URIMAP, named THMF00UR, to supply attributes like host name, server location, listener port, and path string. This avoids specifying this information as part of the INVOKE SERVICE command, plus it makes it easier to change this information as necessary. The OPERATION is required and it reflects the provider application program name, THMF00, suffixed by the word “Operation” in mixed case as you see it.

Next we see the SEND of the REQUEST message being performed, entry numbers =000906= and =000907=. We chose to show the “ENTRY” trace entries since it will show the actual message buffers in the full trace entry, shown next.

Task #137 is the CICS CWXN transaction executing to process the inbound request and invoke the provider application. We chose to only show the RECEIVE command being done, entry numbers =001115= and =001116=. Here we chose to show the “EXIT” trace entries, entry numbers =001115= and =001116=, since these will also show the message buffers, shown later.

Task #138 is the CPIH transaction executing which will run our provider application program, THMF00. Here we chose to show the SEND of the RESPONSE, entry numbers =001663= and =001664=. Once again showing the “ENTRY” trace entries which will contain the message buffers.

Back to task #136 to simply show the “EXIT” entries for the INVOKE SERVICE command being done.

Transaction Profile (MF00) with Trace Entries

69

For task #136, here is the full trace entry =000906=. This is the send of the REQUEST message to the web service provider application. As you can see, its content could be useful at times. Data area 1- is the parameter list, not well documented. Data area 2- is a list of **buffer address/length** pairs. Data area 3- is the data at the first buffer address in the list, maximum of 4000 bytes shown. Data area 4- is the data at the second buffer address in the list.

The information in data area 3- is an **HTTP header** which provides key information about the request. If you look closely you will see the following:

- 1) "POST" – which is the HTTP method being performed
- 2) "/custMaint/THMF00Prov" – which is the path and provider web service name
- 3) "Host: localhost:9083" – which is the host name and listener port

Plus various other information. The format of this data area is document an HTTP manual and not in any CICS documentation.

The information in data area 4- is the actual SOAP envelope which is being sent to the provider location and eventually the provider application. As you can see this is a well-formed XML document which contains the tags and data that makes up the SOAP headers and body. The SOAP body will represent the structure you have defined as part of the DFHLS2WS job.

Transaction Profile (MF00) with Trace Entries

A quick look at a CICS web service (continued):

Here we show task #137 , the CWXN transaction to initial the actual CICS provider task. This trace entry, number =001116=, is the full trace entry for the RECEIVE being done on the CICS server specified in the URIMAP. Data area 1- is the parameter list, not well documented. Data area 2- is the message buffer of the request SOAP message plus the HTTP header. Here you will notice that the HTTP header and SOAP envelope are now contained in a single message buffer.

01E0 3C2F666C 5 (1) Data areas are:
0200 2F544840 4 1 - Parameter list
0220 2D454E56 3 2 - Address/Length pairs of buffers
                                         3 - First buffer (max. 4000)
                                         4 - second buffer (max. 4000)

Here we show task #138, which is the CPIH transaction executing our provider application program, **THMFW00**. This is the **send of the RESPONSE** message back to the requester application. Data area 1- is the parameter list, not well documented. Data area 2- is a list of **buffer address/length** pairs. Data area 3- is the data at the first buffer address in the list, maximum of 4000 bytes shown. Data area 4- is the data at the second buffer address in the list. We have covered these areas in more detail on an earlier slide. The key difference here is that it contains the response message format you specified in the DFHLS2WS job in the SOAP body. Also, a slightly different HTTP header is being returned, which is documented in an HTTP manual.

Summary

- We first took a look at the trace options and resources.
- Next we covered the format of trace entries
- We then covered the use of exception trace entries
- Last we reviewed a few different application profiling opportunities
- Throughout we high-lighted some problem and performance opportunities
