

Lab Overview

In this lab, you will learn how to perform the following tasks with Encryption Facility for z/OS:

- Creating an OpenPGP Keyring
- Creating new RSA key pairs
- Creating OpenPGP certificates
- Exporting OpenPGP certificates
- Encrypting Data
- Decrypting Data
- Generating a certificate and key pair in RACF with the private key in ICSFs PKDS protected by the Master Key
- Connecting a RACF certificate to a RACF keyring
- Using your RACF certificate with Encryption Facility to encrypt data
- Using your private keys from ICSFs PKDS protected by the Master Key to decrypt data
- Exporting your RACF certificate into an OpenPGP certificate
- Invoking EF from USS shell scripts
- Invoking EF from JCL using the JZOS Java Batch Launcher
- Using USS files with EF
- Using datasets with EF
- Modifying EF configuration options
- Signing data with your private key
- Verifying signatures with your public key

Lab Exercise Steps

In steps 1 through 10 you will configure settings for Encryption Facility, generate a new RSA key pair in a Java keystore, generate an OpenPGP certificate, generate an OpenPGP keyring, and export your OpenPGP certificate to the file system.

In many of the steps in this lab you will be modifying preconfigured settings to use your lab user ID. For example, the settings will need to be modified from **sharbxx** to use your lab user ID. The intent is to guide you through the various EF settings and configuration options that are needed to perform EF commands.

1. Logon to the Share Lab System: **mvs1.centers.ihost.com**

TSO logon ID: sharbxx

See Appendix 1 if you need additional help logging on to the share lab system.

Note: Wherever the lab shows sharbxx substitute your userid, e.g. sharb02.

2. Go into OMVS:

OPTION ==> omvs

3. Go to directory, /sharelab/sharbxx/eflab, for the exercises in this lab:

cd /sharelab/sharbxx/eflab

4. List the files in this directory with the unix ls -al command:

ls -al

You should see:

- **CSDEncryptionFacility.jar** - the Encryption Facility for z/OS OpenPGP Jar file
- **ibmef.config** – Encryption Facility for z/OS OpenPGP configuration file
- **data.txt** – a sample data file that you will encrypt in this lab
- **Unix shell scripts** with file extension **.sh** that will be used in the following steps

5. Open the Encryption Facility for z/OS OpenPGP configuration file in oedit to change some of the preconfigured settings.

oedit ibmef.config

Scroll down through the settings to get familiar with all the EF command options.

Modify the KEY_RING_FILENAME location to use your lab user ID. This option specifies the location and name of your EF OpenPGP Keyring.

KEY_RING_FILENAME /sharelab/sharbxx/eflab/ibmpkring.ikr

Modify the JAVA_KEY_STORE_NAME location to use your lab user ID. This option specifies the location and name of your Java Keystore.

JAVA_KEY_STORE_NAME /sharelab/sharbxx/eflab/ibmef.jks

F3 to exit and get back to a command prompt.

Note: If you receive the following message when opening any of the files in this lab just hit enter.

Truncation warning. The data you are editing is variable length data with at least one record that ends with a blank. Saving the data will result in removal of any trailing blanks from all records.

You can issue the PRESERVE ON command if you don't want the blanks removed.

6. Next you will generate an RSA key pair in a Java Keystore and import the public key in OpenPGP certificate format to a new OpenPGP Keyring.

Edit the generateEFKeys.sh shell script.

oedit generateEFKeys.sh

Notice that the location of the z/OS product registration and deregistration services binaries are added to the CLASSPATH and LIBPATH in this shell script and all others used in this lab. This is because EF must register and deregister itself with these services when it runs.

A little further down you will see some local variables that are used by this script.

Modify the EFHOMEDIR variable to use your user ID's lab directory.

EFHOMEDIR=/sharelab/sharbxx/eflab

Modify the key_alias and user_id variables to use your user ID number.

key_alias=sharbxx.key.alias.1

user_id=sharbxx

Down further in the Main section you will find messages printed out by the script indicating what the script is doing, and the actual invocation of the EF command using the variables you just modified from above.

See appendix 3 and 4 for a description of the EF command and options used in this job.

Enter **F3** to save the changes and get back to the command prompt.

7. Generate a new key pair using the generateEFKeys.sh shell script. This script will create a new RSA key pair in a Java keystore in your lab directory. Then it will create an OpenPGP certificate containing the public key and put that into the EF OpenPGP Keyring in your lab directory.

./generateEFKeys.sh

8. Use the list command again to see the new Java keystore and OpenPGP Keyring containing your key material.

ls -al

You should see the Java Keystore with filename, ibmef.jks. This keystore will contain your full RSA key pair.

You should see the OpenPGP Keyring and associated index files with names ibmpkring.ikr, ibmpkring.ikr.kidx, ibmpkring.ikr.uidx. This keyring will contain your public key in OpenPGP certificate format.

9. Next you will export your public key in an OpenPGP certificate to the file system so that it can be shared with other members of the lab.

Edit the exportEFKeys.sh shell script:

oedit exportEFKeys.sh

Modify the EFHOMEDIR to use your lab ID.

EFHOMEDIR=/sharelab/sharbxx/eflab

Modify the user_id variable to use the same user ID you specified in the previous generateEFKeys.sh script. For example:

user_id=sharbxx

See appendix 3 and 4 for a description of the EF command and options used in this job.

Enter F3 to save the changes and get back to the command prompt.

10. Run the exportEFKeys.sh script to export your OpenPGP certificate to the /tmp/eflab directory.

./exportEFKeys.sh

This script also displays the ASCII ARMOR OpenPGP Certificate contents to you.

In steps 11 through 24 you will import other OpenPGP certificates from members of the lab, encrypt data for them, and decrypt data that they have encrypted for you.

11. List the contents of the /tmp/eflab directory to ensure your certificate has been successfully exported to this directory and to also look for other lab members certificates.

ls /tmp/eflab

Your certificate's name should contain your user ID with the .asc file extension.

Write down the name of some of the other certificates you find in the /tmp/eflab directory. You will be importing these into your OpenPGP keyring in the following steps. Then you will use these certificates to exchange encrypted data with other members of the lab. Find out the user ID of the lab member to your left and right so you can use their certificates to encrypt data in the steps later on in this lab.

12. Next you will be importing other lab members OpenPGP certificates from the /tmp/eflab directory.

Open the importEFKeys.sh in oedit.

oedit importEFKeys.sh

Modify the EFHOMEDIR to use your lab ID.

EFHOMEDIR=/sharelab/sharboxx/eflab

Modify the certificates variable to specify the location and names of the certificates you want to import. Optionally, if you want to import all certificates from the /tmp/eflab directory with file extension .asc, leave this variable as is and make no modification.

certificates="\$TMPDIR/*.asc"

Note: If you are specifying multiple certificates separate them with spaces, and make sure to enclose the entire list of certificates with double quotes.

See appendix 3 and 4 for a description of the EF command and options used in this job.

Enter **F3** to save the changes and get back to the command prompt.

13. 13) Run the importEFKeys.sh script to import OpenPGP certificate from the /tmp/eflab directory.

./importEFKeys.sh

14. Next you will use EF's display command to display all of the key material you have generated and imported to this point.

Open the displayEFKeys.sh in oedit.

oedit displayEFKeys.sh

Modify the EFHOMEDIR to use your lab ID.

EFHOMEDIR=/sharelab/sharbxx/eflab

See appendix 3 and 4 for a description of the EF command and options used in this job.

Enter **F3** to save the changes and get back to the command prompt.

15. Run the displayEFKeys.sh script to display all of the key material you have generated and imported to this point.

./displayEFKeys.sh

Take note of and write down the user IDs of the certificates you imported from the /tmp/eflab directory. You will use these user IDs to encrypt data for others in the lab. If you don't already know the user ID of the person to your left and right in the lab, talk to them now to find out their user ID.

Note, if the output from the display script scrolls past the screen display, you can pipe the output to the unix more command to scroll through it. For example, enter **./displayEFKeys.sh | more** at the command prompt and continually press enter to scroll through all of the output.

16. Next you will encrypt data for other members in the lab.

Open the encryptData.sh script in oedit.

oedit encryptData.sh

Modify the EFHOMEDIR to use your lab ID.

EFHOMEDIR=/sharelab/sharbxx/eflab

Modify the user_id variable to use your lab ID.

user_id=sharbxx

Modify the recipients variable to specify all the user IDs you want to encrypt data for. Your data will be encrypted by a symmetric session key, which will be wrapped by each of your recipients public keys. This will produce 1 output file that can be decrypted by each of your recipients. Add your own user ID to the recipient list so that you can decrypt the encrypted file as well.

The recipients list must be enclosed by double quotes and each user ID must be separated by a comma. Do not add spaces between user IDs.

recipients="sharbxx,sharbxx"

See appendix 3 and 4 for a description of the EF command and options used in this job.

Enter **F3** to save the changes and get back to the command prompt.

17. The encryptData.sh script is going to encrypt file data.txt in your eflab directory. Open this file:

oedit data.txt

Add a secret message for your recipients.

Enter **F3** to save the changes and get back to the command prompt.

18. Run the encryptData.sh script:

./encryptData.sh

This script writes the output encrypted file to the /tmp/eflab directory with a file name using your user ID and recipients list. For example, if you specified the user ID sharb01 and the recipients "sharb01,sharb02", the output encrypted file will be named:

/tmp/eflab/data.from.sharb01.to.sharb01,sharb02.ef

19. Open your encrypted file in oedit. For example:

oedit /tmp/eflab/data.from.sharb01.to.sharb01,sharb02.ef

You should see that the encrypted data is a bunch of binary characters that are unreadable.

Do not make any changes to the encrypted data and hit **F3** to exit and go back to a command prompt.

20. Decrypt your encrypted data with your private key.

Open the decryptData.sh script in oedit.

oedit decryptData.sh

Modify the EFHOMEDIR to use your lab ID.

EFHOMEDIR=/sharelab/sharboxx/eflab

Modify the Encryption Facility decrypt command to decrypt the file you just encrypted. For example, if your encrypted file is named /tmp/eflab/data.from.sharb01.to.sharb01,sharb02.ef then the decrypt command should look like this:

\$JAVA6 -jar \$EFJAR -homedir \$EFHOMEDIR -o \$EFHOMEDIR/data.decrypted.txt -d \$TMPDIR/data.from.sharb01.to.sharb01,sharb02.ef

See appendix 3 and 4 for a description of the EF command and options used in this job.

Enter **F3** to save the changes and get back to the command prompt.

21. Run the decryptData.sh script.

./decryptData.sh

This script will decrypt the file to your lab directory using file name data.decrypted.txt. For example:

/sharelab/sharbox/eflab/data.decrypted.txt

22. Open the decrypted file in oedit to ensure it contains your original secret message.

oedit /sharelab/sharbox/eflab/data.decrypted.txt

F3 to exit and go back to a command prompt.

23. Now attempt to decrypt messages from other members in the lab. Since you exported your OpenPGP certificate to the /tmp/eflab directory, the other lab members should have imported your certificate and encrypted their data with it following the instructions from the previous steps. List the files in /tmp/eflab directory and look for encrypted files that are using your user ID.

ls /tmp/eflab

If there are no files for you to decrypt at this time skip to step 25 and come back to this step at the end of the lab.

24. Write down the names of the files that are encrypted using your user ID. Then open back up your decryptData.sh script and modify it to decrypt one of the files that are encrypted for you. You can also modify the output file location so you don't overwrite your previously decrypted message. For example you could specify a new output file like this:

-o \$EFHOMEDIR/data.decrypted2.txt

In steps 25 through 51 you will generate 2 new key pairs using a RACF Keyring that protects the private key with ICSF's MK in the PKDS. Then you will encrypt and sign data with your key pairs and decrypt and verify the signature.

25. Next you will create a RACF Keyring, an RSA key pair that uses ICSF's MK's to protect the private key in the ICSF PKDS, and connect the key pair to the keyring so it can be used from EF. Exit out of OMVS and go back to ISPF. Type **exit** at the command line and hit **enter** at the exit prompt.

Enter option **3.4** to go to the Data Set List Utility.

Enter your lab user ID name followed by .EFLAB.JCL to go to the data set that will be used for this part of the lab.

SHARBxx.EFLAB.JCL

Edit the member named **JZOSVM**. This is a stored procedure that is used to launch the JZOS Java batch launcher. This allows you to kick off a Java program, like EF, from JCL.

This proc is setup to call the EF main class and use the JZOS load module for IBM Java 6.

The JZOS Java batch launcher uses a Java environment script to specify Java settings. The location of this script is specified using the STDENV DD statement toward the bottom of this proc. Update this statement to use your user IDs dataset for this lab.

```
//STDENV DD DSN=SHARBxx.EFLAB.JCL(ENV&VERSION),DISP=SHR
```

Edit the member named **ENV60**. This is the Java environment script that you just updated your JZOSVM proc to use. JZOS will get all of your Java settings from this script. Update the CLASSPATH in this script to use the EF Jar file from your lab user IDs USS lab directory.

Customize your CLASSPATH here

```
CLASSPATH=/usr/include/java_classes/ifaedjreg.jar  
CLASSPATH="$CLASSPATH":/sharelab/sharbx/eflab/  
CLASSPATH="$CLASSPATH"CSDEncryptionFacility.jar
```

F3 and go to option **=6** for the ISPF Command Shell.

From the ISPF command shell enter this command to create a new RACF Keyring using your lab user ID:

```
RACDCERT ID(sharbx) ADDRING(sharbx.eflab.cca.keyring)
```

26. Next you will create a new 2048 bit key pair in RACF using RACDCERTS GENCERT command and the RSA PKDS keywords which specifies a PKDS label name to use for storing the private key. For example:

```
RACDCERT ID(sharbx) GENCERT SUBJECTSDN(CN('sharbx 2048 cert')) SIZE(2048)  
WITHLABEL('sharbx.eflab.cca.cert') RSA (PKDS(sharbx.eflab.cca.cert))
```

27. Then you will connect your new key pair to your RACF keyring and give it a usage type of personal so EF can access the private key.

```
RACDCERT ID(sharbx) CONNECT(ID(sharbx) LABEL('sharbx.eflab.cca.cert')  
RING(sharbx.eflab.cca.keyring) USAGE(PERSONAL))
```

28. Then list out the RACF Keyring and the certificate to ensure the certificate was successfully added.

RACDCERT LISTRING(sharbx.eflab.cca.keyring)

RACDCERT LIST(LABEL('sharbx.eflab.cca.cert'))

29. Now, to your EF Lab dataset, **SHARBxx.EFLAB.JCL**. You are going to update some JCL that is going to invoke EF and use your RACF Keyring and ICSF. First you will edit the **EFDISPL2** member. This JCL calls EF with the display command and the following options that override the ibmef.config EF configuration file. Modify these options to use your USS homedir, your new RACF Keyring name and your RACF user ID. Notice that the keystore type and jce provider list options in this JCL specify to use ICSF and hardware cryptography.

-homedir /sharelab/sharbx/eflab
-keystore sharbx.eflab.cca.keyring
-keystore-type JCECCARACFKS
-racf-keyring-userid sharbx
-jce-providers com.ibm.crypto.hdwrCCA.provider.IBMJCECCA

See appendix 3 and 4 for a description of the EF command and options used in this job.

Go to the SDSF job log by entering **s.st** from the ISPF command prompt and search for the output from the **EFDISPL2** job. Select this job output and scroll to the bottom to see the output from the EF display command. You should see your RACF certificate and your OpenPGP certificates in the output.

30. Next you will modify the **EFEXPOR2** member of your EF Lab dataset. This JCL will export your RACF certificates public key into an OpenPGP certificate. Update the -homedir option to use your USS lab home directory. Update the -keystore and -racf-keyring-userid options like you did in the previous step to use your lab user ID. Update the output file to use your output lab dataset. Specify your new certificate as an argument to the export command.

-homedir /sharelab/sharbx/eflab
-o //SHARBxx.EFLAB.FILES(RACFCER2)
-keystore sharbx.eflab.cca.keyring
-keystore-type JCECCARACFKS
-racf-keyring-userid sharbx
-jce-providers com.ibm.crypto.hdwrCCA.provider.IBMJCECCA
-eA sharbx.eflab.cca.cert

See appendix 3 and 4 for a description of the EF command and options used in this job.

Run this job and it will export the OpenPGP certificate to the data set member named **SHARBxx.EFLAB.FILES(RACFCER2)**.

Browse this data set member to view the certificate.

Check the joblog output to make sure the job ran successfully.

31. Next you will create a new 2048 bit key pair in RACF using RACDCERTS GENCERT command and the RSA PKDS keywords which specifies a PKDS label name to use for storing the private key. This key pair will be used for adding a signature to your encrypted data. For example:

```
RACDCERT ID(sharbxx) GENCERT SUBJECTSDN(CN('sharbxx 2048 cert2')) SIZE(2048)
WITHLABEL('sharbxx.eflab.cca.cert2') RSA (PKDS (sharbxx.eflab.cca.cert2))
```

32. Then you will connect your new key pair to your RACF keyring and give it a usage type of personal so EF can access the private key.

```
RACDCERT ID(sharbxx) CONNECT(ID(sharbxx) LABEL('sharbxx.eflab.cca.cert2')
RING(sharbxx.eflab.cca.keyring) USAGE(PERSONAL))
```

33. Then list out the RACF Keyring and the certificate to ensure the certificate was successfully added.

```
RACDCERT LISTRING(sharbxx.eflab.cca.keyring)
```

```
RACDCERT LIST(LABEL('sharbxx.eflab.cca.cert2'))
```

34. Next you will modify the **EFENCRY2** member of the EF Lab JCL dataset. Update the options to use your USS lab home directory, your new RACF certificates, your lab output files dataset, your RACF keyring, your RACF user ID, and your USS eflab directory.

```
-homedir /sharelab/sharbxx/eflab
-rA sharbxx.eflab.cca.cert
-signers-key-alias sharbxx.eflab.cca.cert2
-o //SHARBxx.EFLAB.FILES(ENCRDAT2)
-keystore sharbxx.eflab.cca.keyring
-keystore-type JCECCARACFKS
-racf-keyring-userid sharbxx
-jce-providers com.ibm.crypto.hdwrCCA.provider.IBMJCECCA
-e -s //SHARBxx.EFLAB.FILES(DATA)
```

See appendix 3 and 4 for a description of the EF command and options used in this job.

Submit this job to encrypt and sign the data with your certificates.

Browse the job output in the EFENCRY2 job in SDSF to ensure it ran successfully.

Browse the encrypted data in **SHARBxx.EFLAB.FILES(ENCRDAT2)**.

35. Next you will decrypt and verify your encrypted and signed data. Modify the **EFDECRY2** member of the EF Lab JCL dataset. Update the options to use your USS lab home directory, your lab output files dataset, your RACF keyring, your RACF user ID, and your encrypted file.

```
-homedir /sharelab/sharbxx/eflab
-o //SHARBxx.EFLAB.FILES(DECRDAT2)
-keystore sharbxx.eflab.cca.keyring
-keystore-type JCECCARACFKS
-racf-keyring-userid sharbxx
-jce-providers com.ibm.crypto.hdwrCCA.provider.IBMJCECCA
-d //SHARBxx.EFLAB.FILES(ENCRDAT2)
```

See appendix 3 and 4 for a description of the EF command and options used in this job.

Submit this job to decrypt and verify the data with your RACF certificates.

Browse the job output in the **EFDECRY2** job in SDSF.

Browse the decrypted data in **SHARBxx.EFLAB.FILES(DECRDAT2)**.

36. Try out JCL dataset member name **EFIMPORT**.

This job will re-import the first RACF certificate that you exported into an OpenPGP certificate.

Check the joblog for results.

Then modify this job to re-import the second RACF certificate you exported into an OpenPGP certificate.

50. Try out JCL dataset member name **EFGENKEY**.

This job will generate a new RSA key pair in your Java keystore and import the public key into your OpenPGP keyring.

Specify a new key alias and user ID.

Check the joblog for results.

51. Look over Appendixes 2, 3 and 4 for EF command syntax and available commands and options. Using the USS shell scripts and JCL jobs from this lab, try out different commands and command options.

Thank You!!!
I hope you enjoyed the lab!!!

Appendix 1

Some commands for the TSO session (3270 interface)

Start emulator

- a. Double Click on the icon provided

This starts a Pcomm 3270 session using **mvs1.centers.ihost.com**.

Note: The **Enter** key is the right **Ctrl** key

Logon to MVS system

- a. When prompted for Userid/ Password/Apl, just enter TSO in the Application field and hit enter
- b. Enter Userid: sharbxx
(Wherever the lab shows sharbxx substitute your userid, e.g. sharb02)
- c. Password: given by the instructor
- d. Hit enter when you see ***, you will be in the ISPF main panel

Logoff from MVS system

- a. Keep hitting PF3 until you are presented with this panel
Log Data Set (SHARBxx.SPFLOG1.LIST) Disposition:
Process Option . . . 1. Print data set and delete
2. Delete data set without printing
3. Keep data set - Same
(allocate same data set in next session)
4. Keep data set - New
(allocate new data set in next session)
- b. Enter option 2
- c. Enter logoff

Open a OMVS session

- a. From ISPF main panel, enter option 6
- b. Enter: **omvs**

Exit a OMVS session

- a. From OMVS shell, type 'exit'

Using the oedit editor / ISPF editor

- a. From OMVS shell, type 'oedit <filename>
- b. From the line numbers columns (on the left side):
i – insert a line (i 20 – insert 20 lines)
c – copy a line
m – move a line
a – paste a line that you've copied using 'c' or moved using 'm' after the current line
d – delete a line (d 20 – delete 20 lines)
- c. From Command ===>
f xx – find the occurrences of xx
c xx yy – change the occurrence of xx to yy (PF6 to repeat the change to the other occurrences)

d. PF3 to save the file and exit (If you want to exit without saving, type 'cancel' on Command==> line)

Appendix 2

EF OpenPGP Command Syntax

All Encryption Facility for OpenPGP commands have the following syntax.

-homedir must appear before all the options, all the options must appear before the commands, and the commands must appear before the arguments.

java -jar CSEncryptionFacility.jar [-homedir name] [options] commands [args]

where:

- **homedir** name is the name of the directory that contains the configuration file `ibmef.config` that contains specified options to use with the command.
- **options** is the name of one or more options to use on the command line and always starts with `-`. These option values override values in the configuration file.
- **commands** is the name of one or more commands and always starts with `-`.
- **arguments** specifies one or more targets of the command, for example, file name, certificate, alias, and so forth.

Appendix 3

EF OpenPGP Commands

-s file

signs an OpenPGP message

-b file

signs an OpenPGP message and create a file containing signature

-e file

encrypts using a session key protected by public key cryptography

-c file

encrypts using a session key protected by a passphrase

-compress file

compresses data into an OpenPGP message

-d file

decrypts an OpenPGP message

-v [detached_signature] signed_file

verifies a signed OpenPGP message

-pP [user_IDs...]

lists information about public keys in key ring file by user ID

-pA [alias...]

lists information about public keys in keystore by alias

-pK [key_ID...]

lists information about public keys in keystore and key ring file by key ID

-g

generates key pair

-i file [file...]

imports OpenPGP certificate(s)

-eP [user_ID...]

exports OpenPGP certificate(s) by user ID(s)

-eK key_ID [key_ID...]

exports OpenPGP certificate(s) by key ID(s)

-eA alias [alias...]

exports OpenPGP certificate(s) by alias(es)

-prepare key_label [key_label...]

prepares Java keystore to use existing keys in ICSF

-xP user_ID [user_ID...]

deletes OpenPGP certificate(s) by user ID(s)

-xK key_ID [key_ID...]

deletes OpenPGP and X.509 certificate(s) by key ID(s)

-xA alias [alias...]

deletes X.509 certificate(s) by alias(es)

-h

displays help information

-list-algo

lists all supported algorithms

-rebuild-key-index

rebuilds index of key ring file

Appendix 4

EF OpenPGP Command Options

-o file
specifies output file

-a
ASCII armor to be used for export

-rP userID_1,userID_2,...,userID_N
recipient's user ID(s)

-rK keyID_1,keyID_2,...,keyID_N
recipient's key ID(s)

-rA alias_1,alias_2,...,alias_N
recipient's alias(es)

-z number
compression
0 - no compression is used
1 - best speed is used
9 - best compression is used
-1 - default compression is used
default value: 0

-t charset
character set
e.g. UTF-8

-comment
comment to be added to ASCII Armor header

-no-save
data is displayed on screen and not saved

-use-embedded-file
unpacked data written to filename specified in data packet

-cipher-name cipher_algo_name
establishes cipher algorithm for encryption
default value: TRIPLE_DES

-digest-name digest_algo_name
establishes digest algorithm for message digest
default value: SHA_1

-compress-name compress_algo_name
establishes compression algorithm for message construction

default value: ZIP

-s2k-cipher-name cipher_algo_name
establishes cipher algorithm for use in PBE
default value: TRIPLE_DES

-s2k-digest-name digest_algo_name
establishes digest algorithm for use in PBE
default value: SHA_1

-s2k-mode 0|1|3
establishes what passphrase based encryption mode to use
0 - plain PBE
1 - Salt based PBE
3 - Salt based PBE with iteration
default value: 3

-s2k-passphrase passphrase
passphrase used for PBE encryption or decryption

-keystore keystore_name
specifies Java keystore filename or RACF key ring name

-keystore-type keystore_type
specifies type of keystore
e.g. JKS,JCECCAKS,JCEKS
default value: "keystore.type" property in the Java security properties file
or the string "JKS" if no such property exists

-keystore-password password
password of keystore

-key-alias key_alias
key pair alias in keystore used for generated (-g) and prepared (-prepare) keys

-key-password key_password
password for key in keystore

-key-size size
key size to use for key generation

-hardware-key-type type
hardware key type to use for hardware key generation

-signers-key-alias key_alias
OpenPGP system key pair alias used for generating signatures

-signers-key-password key_password
password for OpenPGP system key pair alias used for generating signatures

-system-CA-key-alias key_alias

alias used to sign newly generated key pair's certificate

-system-CA-key-password CA_key_password
password for CA key in keystore

-racf-keyring-userid user_ID
specifies user ID for RACF key ring

-trust-value number
assigns trust value to an OpenPGP certificate

-trust-comment
adds comment about trust to an OpenPGP certificate

-log-file file_name
HFS/zFS filename to which trace information is written

-debug mask
takes a mask to activate logging by component

-debug-level number
establishes granularity of debug information

-debug-on
activates debug information which is printed to STDERR while executing

-yes
answers yes to most interactive questions

-no
answers no to most interactive questions

-jce-providers provdr1,provdr2,...,provdrN
specifies the JCE providers to prefix to the provider
list defined in the master security properties file
e.g., com.ibm.crypto.hdwrCCA.provider.IBMJCECCA

-use-mdc
adds a modification detection code packet to encrypted messages

-batch-export
enables batch mode processing for certificate export

-batch-generate algorithm,[number_of_multiples]
enables batch mode processing for key pair generation

-dn-common-name name
specifies the common name of a distinguished name

-dn-country-code country_code
specifies the country code of a distinguished name

-dn-locality locality
specifies the locality of a distinguished name

-dn-organization organization
specifies the organization of a distinguished name

-dn-organization-unit organization_unit
specifies the organization unit of a distinguished name

-dn-state state
specifies the state of a distinguished name

-hidden-key-id
specifies speculative key ID support

-openPGP-days-valid days_valid
specifies the number of days a newly generated OpenPGP certificate is to be valid

-sub-key-alias key_alias
specifies the alias for a new subkey during key generation

-userID-comment comment
specifies a user ID comment for an OpenPGP certificate during key generation and key export

-userID-email email
specifies a user ID email address for an OpenPGP certificate during key generation and key export

-userID-name name
specifies a user ID name for an OpenPGP certificate during key generation and key export

-x509-days-valid days_valid
specifies the number of days an X.509 certificate is to be valid

Appendix 5

RACDCERT Commands

Examples:

```
RACDCERT ID(sharb01) ADDRING(sharb01.eflab.keyring)
```

```
RACDCERT ID(sharb01) GENCERT SUBJECTSDN(CN('sharb01 cert')) SIZE(1024)  
WITHLABEL('sharb01.eflab.racf.cert')
```

```
RACDCERT ID(sharb01) CONNECT(ID(sharb01) LABEL('sharb01.eflab.racf.cert')  
RING(sharb01.eflab.keyring) USAGE(PERSONAL))
```

```
RACDCERT LISTRING(sharb01.eflab.keyring)
```

```
RACDCERT LIST(LABEL('sharb01.eflab.racf.cert'))
```

```
RACDCERT DELRING(sharb01.eflab.keyring)
```

```
RACDCERT DELRING(sharb01.eflab.cca.keyring)
```

```
RACDCERT DELETE(LABEL('sharb01.eflab.racf.cert')) ID(sharb01)
```

```
RACDCERT DELETE(LABEL('sharb01.eflab.cca.cert')) ID(sharb01)
```

```
RACDCERT DELETE(LABEL('sharb01.eflab.cca.cert2')) ID(sharb01)
```

You may need to run the following refresh command for your changes to be reflected by RACF.

```
SETROPTS REFRESH
```
